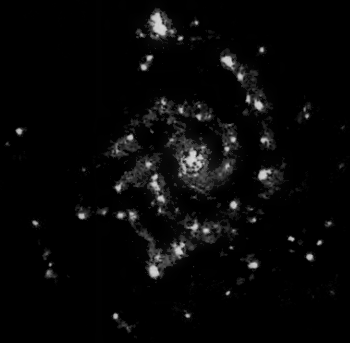
Scientific and Technical Aerospace Reports



An Abstract Journal

Volume 33, Number 6
June 1995
N95-19883 to N95-22477

The NASA STI Office ... in Profile

Since its founding, NASA has been dedicated to the advancement of aeronautics and space science. The NASA Scientific and Technical Information (STI) Office plays a key part in helping NASA maintain this important role.

The NASA STI Office provides access to the NASA STI Database, the largest collection of aeronautical and space science STI in the world. The Office is also NASA's institutional mechanism for disseminating the results of its research and development activities.

Specialized services that help round out the Office's diverse offerings include creating custom thesauri, translating material to or from 34 foreign languages, building customized databases, organizing and publishing research results ... even providing videos.

For more information about the NASA STI Office, you can:

- **Phone** the NASA Access Help Desk at (301) 621-0390
- **Fax** your question to the NASA Access Help Desk at (301) 621-0134
- **E-mail** your question via the **Internet** to help@sti.nasa.gov
- **Write** to:

NASA Access Help Desk
NASA Center for AeroSpace Information
800 Elkridge Landing Road
Linthicum Heights, MD 21090-2934

Scientific and Technical Aerospace Reports

STAR

Scientific and Technical Aerospace Reports (STAR), is published each month as a major product of the NASA Scientific and Technical Information (STI) Office.

Inside this issue you will find:

- **Front Matter** containing a typical citation and abstract sample explaining the standard format, including codes for ordering reports
- **An Abstract Section** containing citations and abstracts of reports and publications that provide comprehensive coverage of worldwide aerospace-related topics including aeronautics and space science technology. *STAR* lists published and publicly available reports entered into the NASA STI Database during the four weeks preceding publication of this issue. These citations and abstracts are listed by subject categories.
- **An Index Section**
    - Subject
    - Personal author
    - Corporate source
    - Contract number
    - Report number
- **An Appendix** containing a guide for ordering cited reports, registering with the NASA STI Office, and using the available products and services. Additionally, price schedules, phone numbers, and addresses are included in this information packed section.

NASA also sponsors the companion journal, *NASA Open Volumes on Aerospace (NOVA)*, which lists abstracts of the open literature on aerospace subjects available worldwide. *NOVA* is for internal NASA use only, available from the NASA Center for AeroSpace Information (CASI).

Entries found in *STAR* are available through the NASA online retrieval service, RECON.

The NASA STI Office gathers information through national and international agreements and exchanges and makes this information available to the NASA community and to the public in many forms through various outlets.

For additional information on the NASA STI Office, call the NASA Access Help Desk at (301) 621-0390, or write to:

TABLE OF CONTENTS

AERONAUTICS For related information see also *Astronautics.*

01 AERONAUTICS (GENERAL) 1199

02 AERODYNAMICS 1199
Includes aerodynamics of bodies, combinations, wings, rotors, and control surfaces; and internal flow in ducts and turbomachinery. For related information see also *34 Fluid Mechanics and Heat Transfer.*

03 AIR TRANSPORTATION AND SAFETY 1202
Includes passenger and cargo air transport operations; and aircraft accidents. For related information see also *16 Space Transportation* and *85 Urban Technology and Transportation.*

04 AIRCRAFT COMMUNICATIONS AND NAVIGATION 1204
Includes digital and voice communication with aircraft; air navigation systems (satellite and ground based); and air traffic control. For related information see also *17 Space Communications, Spacecraft Communications, Command and Tracking* and *32 Communications and Radar.*

05 AIRCRAFT DESIGN, TESTING AND PERFORMANCE 1206
Includes aircraft simulation technology. For related information see also *18 Spacecraft Design, Testing and Performance* and *39 Structural Mechanics.* For land transportation vehicles see *85 Urban Technology and Transportation.*

06 AIRCRAFT INSTRUMENTATION 1208
Includes cockpit and cabin display devices; and flight instruments. For related information see also *19 Spacecraft Instrumentation* and *35 Instrumentation and Photography.*

07 AIRCRAFT PROPULSION AND POWER 1214
Includes prime propulsion systems and systems components, e.g., gas turbine engines and compressors; and onboard auxiliary power plants for aircraft. For related information see also *20 Spacecraft Propulsion and Power, 28 Propellants and Fuels,* and *44 Energy Production and Conversion.*

08 AIRCRAFT STABILITY AND CONTROL 1214
Includes aircraft handling qualities; piloting; flight controls; and autopilots. For related information see also *05 Aircraft Design, Testing and Performance.*

09 RESEARCH AND SUPPORT FACILITIES (AIR) 1215
Includes airports, hangars and runways; aircraft repair and overhaul facilities; wind tunnels; shock tubes; and aircraft engine test stands. For related information see also *14 Ground Support Systems and Facilities (Space).*

ASTRONAUTICS For related information see also *Aeronautics.*

12 ASTRONAUTICS (GENERAL) 1217
For extraterrestrial exploration see *91 Lunar and Planetary Exploration.*

13 ASTRODYNAMICS .... N.A.
Includes powered and free-flight trajectories; and orbital and launching dynamics.

14 GROUND SUPPORT SYSTEMS AND FACILITIES (SPACE) 1218
Includes launch complexes, research and production facilities; ground support equipment, e.g., mobile transporters; and simulators. For related information see also *09 Research and Support Facilities (Air).*

15 LAUNCH VEHICLES AND SPACE VEHICLES 1218
Includes boosters; operating problems of launch/space vehicle systems; and reusable vehicles. For related information see also *20 Spacecraft Propulsion and Power.*

16 SPACE TRANSPORTATION 1219
Includes passenger and cargo space transportation, e.g., shuttle operations; and space rescue techniques. For related information see also *03 Air Transportation and Safety* and *18 Spacecraft Design, Testing and Performance.* For space suits see *54 Man/System Technology and Life Support.*

17 SPACE COMMUNICATIONS, SPACECRAFT COMMUNICATIONS, COMMAND AND TRACKING 1219
Includes telemetry; space communications networks; astronavigation and guidance; and radio blackout. For related information see also *04 Aircraft Communications and Navigation* and *32 Communications and Radar.*

N.A.—No abstracts were assigned to this category for this issue.

18 SPACECRAFT DESIGN, TESTING AND PERFORMANCE 1219
Includes satellites; space platforms; space stations; spacecraft systems and components such as thermal and environmental controls; and attitude controls. For life support systems see *54 Man/System Technology and Life Support.* For related information see also *05 Aircraft Design, Testing and Performance, 39 Structural Mechanics*, and *16 Space Transportation.*

19 SPACECRAFT INSTRUMENTATION 1221
For related information see also *06 Aircraft Instrumentation* and *35 Instrumentation and Photography.*

20 SPACECRAFT PROPULSION AND POWER 1221
Includes main propulsion systems and components, e.g., rocket engines; and spacecraft auxiliary power sources. For related information see also *07 Aircraft Propulsion and Power, 28 Propellants and Fuels, 44 Energy Production and Conversion*, and *15 Launch Vehicles and Space Vehicles.*

CHEMISTRY AND MATERIALS

23 CHEMISTRY AND MATERIALS (GENERAL) 1223

24 COMPOSITE MATERIALS 1224
Includes physical, chemical, and mechanical properties of laminates and other composite materials. For ceramic materials see *27 Nonmetallic Materials.*

25 INORGANIC AND PHYSICAL CHEMISTRY 1233
Includes chemical analysis, e.g., chromatography; combustion theory; electrochemistry; and photochemistry. For related information see also *77 Thermodynamics and Statistical Physics.*

26 METALLIC MATERIALS 1250
Includes physical, chemical, and mechanical properties of metals, e.g., corrosion; and metallurgy.

27 NONMETALLIC MATERIALS 1263
Includes physical, chemical, and mechanical properties of plastics, elastomers, lubricants, polymers, textiles, adhesives, and ceramic materials. For composite materials see *24 Composite Materials.*

28 PROPELLANTS AND FUELS 1281
Includes rocket propellants, igniters and oxidizers; their storage and handling procedures; and aircraft fuels. For related information see also *07 Aircraft Propulsion and Power, 20 Spacecraft Propulsion and Power*, and *44 Energy Production and Conversion.*

29 MATERIALS PROCESSING 1285
Includes space-based development of products and processes for commercial application. For biological materials see *55 Space Biology:*

ENGINEERING For related information see also *Physics.*

31 ENGINEERING (GENERAL) 1285
Includes vacuum technology; control engineering; display engineering; cryogenics; and fire prevention.

32 COMMUNICATIONS AND RADAR 1288
Includes radar; land and global communications; communications theory; and optical communications. For related information see also *04 Aircraft Communications and Navigation* and *17 Space Communications, Spacecraft Communications, Command and Tracking.* For search and rescue see *03 Air Transportation and Safety*, and *16 Space Transportation.*

33 ELECTRONICS AND ELECTRICAL ENGINEERING 1312
Includes test equipment and maintainability; components, e.g., tunnel diodes and transistors; microminiaturization; and integrated circuitry. For related information see also *60 Computer Operations and Hardware* and *76 Solid-State Physics.*

34 FLUID MECHANICS AND HEAT TRANSFER 1337
Includes boundary layers; hydrodynamics; fluidics; mass transfer and ablation cooling. For related information see also *02 Aerodynamics* and *77 Thermodynamics and Statistical Physics.*

35 INSTRUMENTATION AND PHOTOGRAPHY 1363
Includes remote sensors; measuring instruments and gauges; detectors; cameras and photographic supplies; and holography. For aerial photography see *43 Earth Resources and Remote Sensing.* For related information see also *06 Aircraft Instrumentation* and *19 Spacecraft Instrumentation.*

36 LASERS AND MASERS 1368
Includes parametric amplifiers. For related information see also *76 Solid-State Physics.*

37 MECHANICAL ENGINEERING 1377
Includes auxiliary systems (nonpower); machine elements and processes; and mechanical equipment.

38 QUALITY ASSURANCE AND RELIABILITY 1382
Includes product sampling procedures and techniques; and quality control.

39 STRUCTURAL MECHANICS 1384
Includes structural element design and weight analysis; fatigue; and thermal stress. For applications see *05 Aircraft Design, Testing and Performance* and *18 Spacecraft Design, Testing and Performance.*

GEOSCIENCES For related information see also *Space Sciences.*

42 GEOSCIENCES (GENERAL) .... N.A.

43 EARTH RESOURCES AND REMOTE SENSING 1388
Includes remote sensing of earth resources by aircraft and spacecraft; photogrammetry; and aerial photography. For instrumentation see *35 Instrumentation and Photography.*

44 ENERGY PRODUCTION AND CONVERSION 1391
Includes specific energy conversion systems, e.g., fuel cells; global sources of energy; geophysical conversion; and windpower. For related information see also *07 Aircraft Propulsion and Power, 20 Spacecraft Propulsion and Power,* and *28 Propellants and Fuels.*

45 ENVIRONMENT POLLUTION 1400
Includes atmospheric, noise, thermal, and water pollution.

46 GEOPHYSICS 1411
Includes aeronomy; upper and lower atmosphere studies; ionospheric and magnetospheric physics; and geomagnetism. For space radiation see *93 Space Radiation.*

47 METEOROLOGY AND CLIMATOLOGY 1428
Includes weather forecasting and modification.

48 OCEANOGRAPHY 1431
Includes biological, dynamic, and physical oceanography; and marine resources. For related information see also *43 Earth Resources and Remote Sensing.*

LIFE SCIENCES

51 LIFE SCIENCES (GENERAL) 1437

52 AEROSPACE MEDICINE 1441
Includes physiological factors; biological effects of radiation; and effects of weightlessness on man and animals.

53 BEHAVIORAL SCIENCES 1448
Includes psychological factors; individual and group behavior; crew training and evaluation; and psychiatric research.

54 MAN/SYSTEM TECHNOLOGY AND LIFE SUPPORT 1451
Includes human engineering; biotechnology; and space suits and protective clothing. For related information see also *16 Space Transportation.*

55 SPACE BIOLOGY .... N.A.
Includes exobiology; planetary biology; and extraterrestrial life.

MATHEMATICAL AND COMPUTER SCIENCES

59 MATHEMATICAL AND COMPUTER SCIENCES (GENERAL) .... N.A.

60 COMPUTER OPERATIONS AND HARDWARE 1455
Includes hardware for computer graphics, firmware, and data processing. For components see *33 Electronics and Electrical Engineering.*

61 COMPUTER PROGRAMMING AND SOFTWARE 1456
Includes computer programs, routines, algorithms, and specific applications, e.g., CAD/CAM.

62 COMPUTER SYSTEMS 1473
Includes computer networks and special application computer systems.

63 CYBERNETICS **1479**
Includes feedback and control theory, artificial intelligence, robotics and expert systems. For related information see also *54 Man/System Technology and Life Support.*

64 NUMERICAL ANALYSIS **1486**
Includes iteration, difference equations, and numerical approximation.

65 STATISTICS AND PROBABILITY **1497**
Includes data sampling and smoothing; Monte Carlo method; and stochastic processes.

66 SYSTEMS ANALYSIS **1499**
Includes mathematical modeling; network analysis; and operations research.

67 THEORETICAL MATHEMATICS **1500**
Includes topology and number theory.

PHYSICS For related information see also *Engineering.*

70 PHYSICS (GENERAL) **1500**

71 ACOUSTICS **1502**
Includes sound generation, transmission, and attenuation. For noise pollution see *45 Environment Pollution.*

72 ATOMIC AND MOLECULAR PHYSICS **1506**
Includes atomic structure, electron properties, and molecular spectra.

73 NUCLEAR AND HIGH-ENERGY PHYSICS **1531**
Includes elementary and nuclear particles; and reactor theory. For space radiation see *93 Space Radiation.*

74 OPTICS **1540**
Includes light phenomena and optical devices. For lasers see *36 Lasers and Masers.*

75 PLASMA PHYSICS **1548**
Includes magnetohydrodynamics and plasma fusion. For ionospheric plasmas see *46 Geophysics*. For space plasmas see *90 Astrophysics.*

76 SOLID-STATE PHYSICS **1563**
Includes superconductivity. For related information see also *33 Electronics and Electrical Engineering* and *36 Lasers and Masers.*

77 THERMODYNAMICS AND STATISTICAL PHYSICS **1579**
Includes quantum mechanics; theoretical physics; and Bose and Fermi statistics. For related information see also *25 Inorganic and Physical Chemistry* and *34 Fluid Mechanics and Heat Transfer.*

SOCIAL SCIENCES

80 SOCIAL SCIENCES (GENERAL) **1583**
Includes educational matters.

81 ADMINISTRATION AND MANAGEMENT **1583**
Includes management planning and research.

82 DOCUMENTATION AND INFORMATION SCIENCE **1586**
Includes information management; information storage and retrieval technology; technical writing; graphic arts; and micrography. For computer documentation see *61 Computer Programming and Software.*

83 ECONOMICS AND COST ANALYSIS **1594**
Includes cost effectiveness studies.

84 LAW, POLITICAL SCIENCE AND SPACE POLICY .... **N.A.**
Includes NASA appropriation hearings; aviation law; space law and policy; international law; international cooperation; and patent policy.

85 URBAN TECHNOLOGY AND TRANSPORTATION **1594**
Includes applications of space technology to urban problems; technology transfer; technology assessment; and surface and mass transportation. For related information see *03 Air Transportation and Safety, 16 Space Transportation,* and *44 Energy Production and Conversion.*

SPACE SCIENCES For related information see also *Geosciences*.

88 SPACE SCIENCES (GENERAL) **1595**

89 ASTRONOMY **1598**
Includes radio, gamma-ray, and infrared astronomy; and astrometry.

90 ASTROPHYSICS **1599**
Includes cosmology; celestial mechanics; space plasmas; and interstellar and interplanetary gases and dust. For related information see also *75 Plasma Physics.*

91 LUNAR AND PLANETARY EXPLORATION **1601**
Includes planetology; and manned and unmanned flights. For spacecraft design or space stations see *18 Spacecraft Design, Testing and Performance.*

92 SOLAR PHYSICS **1602**
Includes solar activity, solar flares, solar radiation and sunspots. For related information see also *93 Space Radiation.*

93 SPACE RADIATION **1604**
Includes cosmic radiation; and inner and outer earth's radiation belts. For biological effects of radiation see *52 Aerospace Medicine.* For theory see *73 Nuclear and High-Energy Physics.*

GENERAL

Includes aeronautical, astronautical, and space science related histories, biographies, and pertinent reports too broad for categorization; histories or broad overviews of NASA programs.

The effects of a forward-swept front rotor on the flowfield of a counterrotation model propeller at takeoff conditions at zero degree angle of attack are studied by solving the unsteady three-dimensional Euler equations. The configuration considered is an uneven blade count counterrotation model with twelve forward-swept blades on the fore rotor and ten aft-swept blades on the aft rotor. The flowfield is compared with that of a reference aft-swept counterrotation geometry and Laser Doppler Velocimeter (LDV) measurements. At the operating conditions considered, the forward-swept blade experiences a higher tip loading and produces a stronger tip vortex compared to the aft-swept blade, consistent with the LDV and acoustic measurements. Neither the solution nor the LDV data indicated the formation of a leading edge vortex. The predicted radial distribution of the circumferentially averaged axial velocity at the measurement station agreed very closely with LDV data, while crossflow velocities showed poor agreement. The discrepancy between prediction and LDV data of tangential and radial velocities is due in part to the insufficient mesh resolution in the region between the rotors and in the tip region to track the tip vortex. The vortex is diffused by the time it arrives at the measurement station. The uneven blade count configuration requires the solution to be carried out for six blade passages of the fore rotor and five passages of the aft rotor, thus making grid refinement prohibitive.

DAMAGE TOLERANT REPAIR TECHNIQUES FOR PRESSURIZED AIRCRAFT FUSELAGES Final Report, 15 Jun. 1991 - 15 Nov. 1993
Robert S. Fredell 6 Jun. 1994 281 p
(AF Proj. 2401)
(AD-A286298; WL-TR-94-3134) Avail: CASI HC A13/MF A03

Concerns over the safety of the continued use of aging transport aircraft have been voiced in the industry. A key component in the structural integrity of aging aircraft is the damage tolerance of fuselage structural repairs. The investigation focuses on the analysis and testing of contemporary repair methods and develops two improvements. The first technique, known as soft patching, is appropriate for damage tolerant riveted repairs to incidental fuselage damage. Soft patching involves the use of high strength, moderate elastic modulus GLARE 3 fiber metal laminate patches. They extend the fatigue life of riveted repairs to monolithic aluminum fuselages while reducing life cycle costs. The second technique involves bonded crack patching of intact fatigue cracks in fuselage skins. An easy to use analysis program is presented along with analytical and test results of a low cost, high performance patch material known as GLARE 2. The findings demonstrate that GLARE 2 can replace the expensive boron/epoxy composites used in fuselage crack patching applications. DTIC

02 AERODYNAMICS

Includes aerodynamics of bodies, combinations, wings, rotors, and control surfaces; and internal flow in ducts and turbomachinery.

STATIC INVESTIGATION OF TWO FLUIDIC THRUST-VECTORING CONCEPTS ON A TWO-DIMENSIONAL CONVERGENT-DIVERGENT NOZZLE
David J. Wing Dec. 1994 203 p
(RTOP 505-62-30-01)
(NASA-TM-4574; L-17350; NAS 1.15:4574) Avail: CASI HC A10/MF A03

A static investigation was conducted in the static test facility of the Langley 16-Foot Transonic Tunnel of two thrust-vectoring concepts which utilize fluidic mechanisms for deflecting the jet of a two-dimensional convergent divergent nozzle. One concept involved using the Coanda effect to turn a sheet of injected secondary air along a curved sidewall flap and, through entrainment, draw the primary jet in the same direction to produce yaw thrust vectoring. The other concept involved deflecting the primary jet to produce pitch thrust vectoring by injecting secondary air through a transverse slot in the divergent flap, creating an oblique shock in the divergent channel. Utilizing the Coanda effect to produce yaw thrust vectoring was largely unsuccessful. Small vector angles were produced at low primary nozzle pressure ratios, probably because the momentum of the primary jet was low. Significant pitch thrust vector angles were produced by injecting secondary flow through a slot in the divergent flap. Thrust vector angle decreased with increasing nozzle pressure ratio but moderate levels were maintained at the highest nozzle pressure ratio tested. Thrust performance generally increased at low nozzle pressure ratios and decreased near the design pressure ratio with the addition of secondary flow. Author

N95-19946# Aircraft Research Association Ltd., Bedford (England).
INVESTIGATION OF A THERMAL BUOYANCY EFFECT ON THE DRAG OF HALF MODELS TESTED IN THE ARA TRANSONIC WIND TUNNEL
Dennis R. Stanniland, Ian F. Burns, and John E. Green May 1994 12 p Presented at the 19th Congress of the International Council of the Aeronautical Sciences, Anaheim, CA, Sep. 1994
(ARA-Memo-407) Avail: CASI HC A03/MF A01

The demand for improved drag repeatability from wind tunnel measurements, together with the increasing size of models (driven by the requirement for accurate representation of small components), has led to the need for a greater understanding of the flow near the porous walls of the ARA Transonic Wind Tunnel and the implications of very small changes in this flow on the model force measurements. A detailed investigation of the variability of drag measurements on a half model identified a diurnal variation which could be attributed to the small changes in temperature difference between the tunnel shell and the freestream. This paper describes measurements which have been made in the tunnel to identify the cause of this non-repeatability. The results show a variation in the boundary layer development on the tunnel walls caused by differences in the heat transfer in the plenum chamber. This can change the Mach number in the vicinity of a half model afterbody by approximately 0.002 for a temperature increment of 5 deg K, implying a change in drag coefficient 0f 0.0002 for a typical civil aircraft model. An extension to the test section has been designed, which was successful in removing the thermal influence on the boundary layer thickness and centerline Mach number in the empty tunnel. However, some thermal buoyancy remains when a half model is tested in the redesigned section, although this is significantly reduced for a large model. A correction procedure has been developed which has virtually eliminated thermal buoyancy as a source of error, resulting in a drag repeatability of better than 1 count. Author

OPEN SKIES PROJECT COMPUTATIONAL FLUID DYNAMIC ANALYSIS Final Report, Nov. 1992 - May 1993
James C. Slavey, Mark S. Jurkovich, Robert M. Weyer, and Joseph C. Zuppardo Mar. 1994 130 p
(AD-A285928; ASC-TR-94-5027) Avail: CASI HC A07/MF A02

A Computational Fluid Dynamic (CFD) analysis has been performed on a WC-135B aircraft that has been modified at Wright-Patterson AFB (WPAFB) forming the first Open Skies aircraft designated OC-135B. The studies included the use of panel method, full potential, and Navier-Stokes methods utilizing 2-D/axisymmetric, and 3-D. While providing information useful to the Open Skies program, the studies also provide a good example of how lower order and higher order computational aerodynamic methods can be used together to obtain the maximum benefit from CFD at a minimum cost. Flight test tufting and accelerometer data confirmed the results of the 3-D Full Navier-Stokes results. DTIC

F-16XL INTERVIEW WITH MARTA BOHN-MEYER (Videotape)
27 Jul. 1992 Videotape: 30 min. playing time, in color, with sound
(NASA-TM-110505; NONP-NASA-VT-95-41117) Avail: CASI VHS A02/BETA A22

Marta Bohn-Meyer discusses the cooperative research between Rockwell Industries and NASA research facilities in their effort to optimize and maintain the supersonic laminar flow on the F-16XL aircraft. Research on the airfoil design, chord optimization, introduction of a suction feature to maintain pressure distribution, and CFD, both theoretical and actual phenomena, are discussed. Bohn-Meyer discusses the difference between supersonic and subsonic laminar flow, cross flow, reasons behind using this particular F-16 aircraft for this research, and the future of this ongoing research, including the data base that investigators are building from wind tunnel data and in-flight validation. FREE SHEAR LAYERS, BASE PRESSURE AND BLUFF-BODY DRAG
A. Roshko 10 Dec. 1993 19 p
(Contract N00014-94-1-0793)
(AD-A286316) Avail: CASI HC A03/MF A01

Incompressible, non-vortex-shedding bluff-body flows and supersonic base-pressure flows are discussed from a unified viewpoint in which the aspect ratio of the near wake is determined from the balance of shear-stress and pressure forces on the near-wake boundary. The base pressure and drag are then determined from free-streamline theory. The analysis is incomplete, for want of sufficient information about conditions in reattaching supersonic turbulent shear layers. Author (DTIC)

N95-20177 California Inst. of Tech., Pasadena, CA. Graduate Aeronautical Labs.
RESEARCH ON BLUFF BODY VORTEX WAKES
Anatol Roshko, Anthony Leonard, and Morteza Gharib 1994 8 p
Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-94-1-0793)
(AD-A286319) Avail: CASI HC A02

The basic approach is to obtain measurements in correlated laboratory experiments and numerical simulations of flows past bluff bodies, especially circular cylinders. Laboratory measurements include flow visualization and digital particle image velocimetry (DPIV). Numerical simulations are based on vortex methods. Interpretation of relations between velocity/vorticity fields and body forces is sought through the generalized Biot-Savart law. The role of Reynolds number, effects of three dimensionality, and effects of body motion are investigated. Relations to the mean near-wake flow and mean force (drag) are also studied, for their basic technological importance and also for insights into the unsteady motion. DTIC

N95-20248# Arnold Engineering Development Center, Arnold AFS, TN.
DESCRIPTION AND FLOW CHARACTERIZATION OF HYPERSONIC FACILITIES Final Report, Jul. 1992 - Jul. 1993
A. Anderson, R. K. Matthews, J. R. Maus, and R. A. Crawford Aug. 1994 59 p
(AD-A284291; AEDC-TR-94-8) Avail: CASI HC A04/MF A01

Hypersonic test facilities will continue to play a major role in the development of hypersonic vehicles. In the past, ground test facilities were often used to perform configuration parametric studies and/or to develop large databases. Future testing will emphasize understanding of fluid physics and validation of codes. Computational fluid dynamics (CFD) has made great progress in the past two decades, but the marriage of CFD and ground testing is clearly a reality today, and will become even more important in the future. One of the challenges for the experimentalist is to develop and utilize facilities that simulate hypersonic flight, and to provide the required data precision to validate CFD codes. This provides a brief review of facility fundamental considerations and simulation issues. It is clear that no one facility will meet the wide variety of test objectives; therefore, the test facilities span a range of size, run time, complexity, and operating cost. Representative facilities are described, as well as their test capabilities, and shortfalls. DTIC

Paper summarizes the status of personal air transportation with emphasis upon VTOL and converticar capability. The former obviates the need for airport operations for personal aircraft whereas the latter provides both ground and air capability in the same vehicle. Fully automatic operation, ATC and navigation is stressed along with consideration of acoustic, environmental and cost issues. Author

THE DYNAMIC APPROACH TO ROTOR BLADE RESEARCH: ARA'S OSCILLATORY TEST FACILITY
Caroline M. Humphreys Sep. 1994 12 p Presented at the ICAS 1994, Anaheim, CA, Sep. 1994 Original contains color illustrations
(ARA-Memo-405) Avail: CASI HC A03/MF A01 color page

Helicopters' forward flight performance is limited by the rapid build up in blade and control loads which occur when rotor blades enter stall conditions. Due to a combination of the helicopter forward speed and the rotor rotational velocity the rotor sections experience a wide range of local onset conditions, this leads to vastly different flow characteristics across the span and through the rotational cycle. A great deal of time and effort has been devoted to studying this flow phenomena. Consequently, information covering all aspects of unsteady aerodynamics is easily available. However, one area that needs up-dating is the description of the experimental test facilities that are able to simulate these flow conditions. The dynamic rig at the Aircraft Research Association was designed and built in the 1970's. Since then, as new technology became available, the rig's capabilities have been steadily improved. The paper reports on these amendments. Author

It is well known in the aerodynamic field that pressure distribution measurement over the surface of an aircraft model is a problem in experimental aerodynamics. For one thing, a continuous pressure map can not be obtained with the current experimental methods since they are discrete. Therefore, interpolation or CFD methods must be used for a more complete picture of the phenomenon under study. For this study, a new technique was investigated which would provide a continuous pressure distribution over the surface under consideration. The new method is pressure sensitive paint. When pressure sensitive paint is applied to an aerodynamic surface and placed in an operating wind-tunnel under appropriate lighting, the molecules luminesce as a function of the local pressure of oxygen over the surface of interest during aerodynamic flow. The resulting image will be brightest in the areas of low pressure (low oxygen concentration), and less intense in the areas of high pressure (where oxygen is most abundant on the surface). The objective of this investigation was to use pressure sensitive paint samples from McDonnell Douglas (MDD) for calibration purpose in order to assess the response of the paint under appropriate lighting and to use the samples over a flat plate/conical fin mounted at 75 degrees from the center of the plate in order to study the shock/boundary layer interaction at Mach 6 in the Von Karman wind-tunnel. From the result obtained it was concluded that temperature significantly affects the response of the paint and should be given the uppermost attention in the case of hypersonic flows. Also, it was found that past a certain temperature threshold, the paint intensity degradation became irreversible. The comparison between the pressure tap measurement and the pressure sensitive paint showed the right trend. However, there exists a shift when it comes to the actual value. Therefore, further investigation is under way to find the cause of the shift. Author

WAKE MEASUREMENTS IN A STRONG ADVERSE PRESSURE GRADIENT

R. Hoffenberg, John P. Sullivan, and S. P. Schneider 1994 13 p
(Grant NAG2-854)
(NASA-CR-197272; NAS 1.26:197272; AIAA Paper 94-2613) Avail: CASI HC A03/MF A01

The behavior of wakes in adverse pressure gradients is critical to the performance of high-lift systems for transport aircraft. Wake deceleration is known to lead to sudden thickening and the onset of reversed flow; this 'wake bursting' phenomenon can occur while surface flows remain attached. Although 'wake bursting' is known to be important for high-lift systems, no detailed measurements of 'burst' wakes have ever been reported. Wake bursting has been successfully achieved in the wake of a flat plate as it decelerated in a two-dimensional diffuser, whose sidewalls were forced to remain attached by use of slot blowing. Pilot probe surveys, L.D.V. measurements, and flow visualization have been used to investigate the physics of this decelerated wake, through the onset of reversed flow. Author

APPLICATION OF NAVIER-STOKES CODE PAB3D WITH KAPPA-EPSILON TURBULENCE MODEL TO ATTACHED AND SEPARATED FLOWS

Khaled S. Abdol-Hamid (Analytical Services and Materials, Inc., Hampton, VA.), B. Lakshmanan (Old Dominion Univ., Norfolk, VA.), and John R. Carlson Jan. 1995 43 p
(RTOP 505-59-10-20)
(NASA-TP-3480; L-17354; NAS 1.60:3480) Avail: CASI HC A03/MF A01

A three-dimensional Navier-Stokes solver was used to determine how accurately computations can predict local and average skin friction coefficients for attached and separated flows for simple experimental geometries. Algebraic and transport equation closures were used to model turbulence. To simulate anisotropic turbulence, the standard two-equation turbulence model was modified by adding nonlinear terms. The effects of both grid density and the turbulence model on the computed flow fields were also investigated and compared with available experimental data for subsonic and supersonic free-stream conditions. EXPERIMENTS ON THE FLOW FIELD PHYSICS OF CONFLUENT BOUNDARY LAYERS FOR HIGH-LIFT SYSTEMS Progress Report

Robert C. Nelson, F. O. Thomas, and H. C. Chu [1994] 18 p Original contains color illustrations
(Grant NAG2-905)
(NASA-CR-197318; NAS 1.26:197318) Avail: CASI HC A03/MF A01; 3 functional color pages

The use of sub-scale wind tunnel test data to predict the behavior of commercial transport high lift systems at in-flight Reynolds number is limited by the so-called 'inverse Reynolds number effect'. This involves an actual deterioration in the performance of a high lift device with increasing Reynolds number. A lack of understanding of the relevant flow field physics associated with numerous complicated viscous flow interactions that characterize flow over high-lift devices prohibits computational fluid dynamics from addressing Reynolds number effects. Clearly there is a need for research that has as its objective the clarification of the fundamental flow field physics associated with viscous effects in high lift systems. In this investigation, a detailed experimental investigation is being performed to study the interaction between the slat wake and the boundary layer on the primary airfoil which is known as a confluent boundary layer. This little-studied aspect of the multi-element airfoil problem deserves special attention due to its importance in the lift augmentation process. The goal of this research is is to provide an improved understanding of the flow physics associated with high lift generation. This process report will discuss the status of the research being conducted at the Hessert Center for Aerospace Research at the University of Notre Dame. The research is sponsored by NASA Ames Research Center under NASA grant NAG2-905. The report will include a discussion of the models that have been built or that are under construction, a description of the planned experiments, a description of a flow visualization apparatus that has been developed for generating colored smoke for confluent boundary layer studies and some preliminary measurements made using our new 3-component fiber optic LDV system. A PRELIMINARY STUDY OF THE AIRWAKE MODEL USED IN AN EXISTING SH-60B/FFG-7 HELICOPTER/SHIP SIMULATION PROGRAM

Lincoln P. Erm May 1994 44 p
(DSTO-TR-0015; AR-008-644) Copyright Avail: Issuing Activity (DSTO Aeronautical and Maritime Research Lab., GPO Box 4331, Melbourne, Victoria 3001, Australia)

The ship airwake model in a SH-60B/FFG-7 helicopter/ship simulation program is studied in detail. The airwake model is based on wind tunnel measurements obtained for another ship type, with geometric scaling applied to make it suitable for an FFG-7 frigate. Velocities over the flight deck of an FFG-7, predicted using the program, are compared with those obtained from full-scale tests on HMAS Darwin. Differences between predicted and measured velocities are often found to occur, indicating that the model used for prediction should be based on measurements for an FFG-7. Author

PRESSURE MEASUREMENTS ON AN F/A-18 TWIN VERTICAL TAIL IN BUFFETING FLOW. VOLUME 1: WIND TUNNEL TEST SUMMARY Final Report, Apr. 1993 - Aug. 1994
Chris Pettit, Michael Banford, Dansen Brown, and Ed Pendleton 31 Aug. 1994 105 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A279126; WL-TM-94-3039-Vol-1) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Buffeting pressure measurements were made on the vertical tail surface of a full scale F/A-18 aircraft model in the National Full Scale Aerodynamics Complex at NASA Ames Research Center. Test variables included aircraft angle-of-attack, aircraft sideslip angle, and dynamic pressure. Accelerometers were used to obtain vertical tail accelerations. Pressure transducers were mounted on the starboard vertical tail. Steady and unsteady pressures were obtained. Unsteady pressure data were reduced to power spectral density (PSD) and cross spectral density (CSD) forms. Both steady and unsteady RMS pressure coefficients are also presented. Volume 1 contains the general description of the model, the test program, and highlights of the reduced data. DTIC

A REVIEW OF WATER MIST TECHNOLOGY FOR FIRE SUPPRESSION Memorandum Report
P. A. Tatum, C. L. Beyler (Hughes Associates, Inc., Columbia, MD.), P. J. DiNenno (Hughes Associates, Inc., Columbia, MD.), E. K. Budnick (Hughes Associates, Inc., Columbia, MD.), and G. G. Back (Hughes Associates, Inc., Columbia, MD.) 30 Sep. 1994 93 p
(NR Proj. RH2-1-S-22)
(AD-A285738; NRL/MR/6180-94-7624) Avail: CASI HC A05/MF A01

The potential efficacy of water mist fire suppression systems has been demonstrated in a wide range of applications and by numerous experimental programs. These applications have included Class B spray and pool fires, aircraft cabins, shipboard machinery and engine room spaces, shipboard accommodation spaces, and computer and electronics applications. To summarize these experimental efforts, the efficacy of a particular water mist system is strongly dependent on the ability to not only generate sufficiently small droplet sizes but also distribute sufficient mist concentrations throughout the compartment. A widely accepted critical concentration of water droplets required to extinguish a fire is yet to be determined. Factors that contribute to the success or failure of a water mist system for a particular application include droplet size, velocity, the spray pattern geometry as well as the momentum and mixing characteristics of the spray jet, and the geometry and other characteristics of the protected area. At this time, the effect of these factors on system effectiveness is not well known. This will necessitate evaluation of water mist in context of a specific system for unique applications for the reasonable future unless breakthroughs in understanding of mist distribution and flame interaction occur through research. Presented are a compilation of data collected at Northwest Airlines terminal, General Mitchell International Airport, Milwaukee, Wisconsin, from February 22-24, 1994. The study was conducted in support of the Aviation Security Human Factors Research Program located at the Federal Aviation Administration Technical Center (FAATC), Atlantic City International Airport, New Jersey. Real-time (e.g., at the ticket counter and gate) passenger profiling was conducted February 22-24, 1994 in Milwaukee, Wisconsin. Passengers on twenty-one Northwest Airline flights were profiled according to parameters set forth by the Passenger Profiling Subject Matter Expert panel. One hundred ten passengers (82.7%) were cleared by the profile; twenty-three (17.3%) were not cleared. The mean time to profile was 1 minute 23 seconds. An analysis of variance (ANOVA) and a subsequent least square difference (LSD) multiple comparison showed it took significantly longer to profile passengers who were not cleared (mean = 1 minute 27 seconds) than to profile passengers who were cleared (mean = 1 minute 9 seconds) (F(131, 1) = 36.87, p = .000). Interview and anecdotal data are also summarized. DTIC

COMMUTER AIRPLANE ACCIDENT DATA ANALYSIS Final Report
G. Wittlin Aug. 1994 34 p
(Contract DTFA03-89-C-00043)
(AD-A286315; DOT/FAA/CT-94/75) Avail: CASI HC A03/MF A01

This report presents the results of a review of data from 120 commuter and air taxi airplane accidents that occurred from 1978 through 1986. The main objectives of this study are (1) to present the severe, but survivable impact condition data from the accident database and (2) to formulate appropriate crash design impact parameters. In 1980 the Federal Aviation Administration Technical Center (FAATC) initiated the Aircraft Crashworthiness Program, which resulted in a compilation of commuter airplane accident data. The program's objectives were (1) to define potentially survivable commuter airplane crash scenarios and (2) to provide impact parameters associated with the appropriate crash scenarios. Based on the data that was received, a crash survivable design envelope was defined for commuter airplanes. DTIC

COMMUTER/AIR TAXI DITCHINGS AND WATER-RELATED IMPACTS THAT OCCURRED FROM 1979 TO 1989 Final Report, Jun. 1990 - Dec. 1992
Charles C. Chen and Mark Muller Jul. 1994 105 p
(Contract DTFA03-89-C-00043)
(AD-A285691; DOT/FAA/CT-92/4) Avail: CASI HC A06/MF A01

This report documents an investigation of ditchings and water-related impacts for commuter-category aircraft that occurred during the years 1979 through 1989. The main source of accident data was the National Transportation Safety Board (NTSB). Data were also sought from the International Civil Aviation Organization and the U.S. Navy Safety Center. A total of 46 accidents was obtained and examined for this study. Of these, 40 cases satisfied the criteria for inclusion into the database. Impact and post-impact conditions were categorized to assess aircraft behavior and occupant survivability. Two impact scenarios and two post-impact scenarios were established. Special emphasis was placed on examining aircraft flotation behavior and post-impact survivability. In addition, five representative case studies are presented to demonstrate aspects peculiar to the commuter-category aircraft water impact and post-impact sequence that could not be adequately covered by the statistical categorizations alone. DTIC

WHY DO AIRLINES WANT AND USE THRUST REVERSERS? A COMPILATION OF AIRLINE INDUSTRY RESPONSES TO A SURVEY REGARDING THE USE OF THRUST REVERSERS ON COMMERCIAL TRANSPORT AIRPLANES

Jeffrey A. Yetter Jan. 1995 65 p
(RTOP 538-05-13-01)
(NASA-TM-109158; NAS 1.15:109158) Avail: CASI HC A04/MF A01

Although thrust reversers are used for only a fraction of the airplane operating time, their impact on nacelle design, weight, airplane cruise performance, and overall airplane operating and maintenance expenses is significant. Why then do the airlines want and use thrust reversers? In an effort to understand the airlines need for thrust reversers, a survey of the airline industry was made to determine why and under what situations thrust reversers are currently used or thought to be needed. The survey was intended to help establish the cost/benefits trades for the use of thrust reversers and airline opinion regarding alternative deceleration devices. A compilation and summary of the responses given to the survey questionnaire is presented. Author

INDEPENDENT REVIEW OF AVIATION TECHNOLOGY AND RESEARCH INFORMATION ANALYSIS SYSTEM (ATRIAS) DATABASE Final Report

Ronald J. Lofaro, L. Hitchcock, S. L. Boggs, and J. E. Mateski Feb. 1994 92 p
(Contract DTFA01-93-P-02265)
(AD-A284049; DOT/FAA/CT-94/12) Avail: CASI HC A05/MF A01

This technical report presents the findings of a critical review of the Aviation Technology and Research Information Analysis System (ATRIAS) for its capability to support the Federal Aviation Administration (FAA)/Aviation Security Research and Development Service's (ACA) Explosive Detection Systems (EDS) programs and Aviation Security Human Factors Program (ASHFP). This review was conducted by an independent consultant selected by the FAA. Section 1 of the report gives a descriptive overview of the ATRIAS analysis and reporting system. The findings of the independent review are contained in sections 2 and 3 of the report. Overall, ATRIAS was found to address many technology application areas relevant to the FAA's aviation security programs. However, the findings did recommend specific modifications to ATRIAS that will provide enhanced information collection and analysis for six topic areas of prime relevance to the FAA's EDS and ASHFP programs. RADAR STUDIES OF AVIATION HAZARDS

F. I. Harris, Ralph S. Donaldson, Jr., David J. Smalley, and Shu-Lin Tung 31 May 1994 94 p
(Contract F19628-93-C-0054)
(AD-A285845; PL-TR-94-2146; SR-1) Avail: CASI HC A05/MF A01

During the first year of this contract, research was directed toward the development of new techniques to monitor and forecast weather related aviation hazards with Doppler weather radar. Focus was on the characterization of the structure of severe convective storms and of synoptic scale baroclinic fronts. One aspect that was examined is the detection and quantization of the weak echo region usually seen in severe convective storms. Another has been the search for lightning precursors. Finally, considerable effort has been expended on the automated depiction of the wind and precipitation structure associated with baroclinic fronts. DTIC

ANALYSIS OF TEST CRITERIA FOR SPECIFYING FOAM FIREFIGHTING AGENTS FOR AIRCRAFT RESCUE AND FIREFIGHTING Final Report

Joseph L. Scheffey and Joseph A. Wright Aug. 1994 96 p Sponsored by FAA
(AD-A286381; DOT/FAA/CT-94/04) Avail: CASI HC A05/MF A01

Foam agent quantities and application rates for FAA certified airports are based on large-scale fire test data of Aqueous Film-Forming Foam (AFFF) and protein-based foams. The philosophy is to control aircraft fuel fires in sixty seconds. Foam agents which are used for aviation applications should demonstrate this level of performance, including a safety factor which assures adequate performance under less than optimum conditions. A review of standard test methods and performance criteria indicates a wide range of requirements. The U.S. Military Specification (MIL SPEC) for AFFF, on which the original agent criteria was developed, is the most stringent in terms of extinguishment application density. However, no direct correlation has been demonstrated between many of the required physical/chemical properties tests and fire extinguishment/burnback performance. It was demonstrated, using comparative data from numerous small and large-scale fire tests, that the small-scale MIL SPEC fire tests correlate with large-scale test results. MIL SPEC agents, which provide a safety factor over minimum FAA requirements, also are formulated to have proportioning, storage, stability, and shelf-life attributes appropriate for crash rescue firefighting applications. Adoption of the MIL SPEC for AFFF agents is recommended. Future work related to foam testing should focus on the use of first principles to establish fundamental foam extinguishment mechanisms. DTIC

FORECASTING AIRCRAFT MISHAPS USING MONTHLY MAINTENANCE REPORTS M.S. Thesis

John S. VanHouten Sep. 1994 73 p
(AD-A286049) Avail: CASI HC A04/MF A01

Naval Aviation aircraft mishaps continue to be of great concern due to the high cost of loss of life and aircraft. The goal of this thesis is to develop a predictive statistical model that accurately forecasts Marine Corps AV-8B Harrier aircraft mishaps based on existing monthly maintenance reports. Monthly maintenance reports provide numerous independent variables based on personnel levels and maintenance hours that could possibly be used to forecast aircraft mishaps. These variables were graphically analyzed to determine any relationships that could be exploited in developing the model. Higher order relationships were investigated by the method of principal components and logistic regression. After a thorough analysis, there appears to be no combination of variables in this particular data that could be used to forecast aircraft mishaps. The overall result of the thesis is that there is no relationship between monthly maintenance reports and aircraft mishaps that can be exploited to develop a predictive statistical model. DTIC

CREW AIDING AND AUTOMATION: A SYSTEM CONCEPT FOR TERMINAL AREA OPERATIONS, AND GUIDELINES FOR AUTOMATION DESIGN Final Report
John P. Dwyer Dec. 1994 216 p
(Contract NAS1-18028; RTOP 505-64-13-22)
(NASA-CR-4631; NAS 1.26:4631; CRAD-9206-TR-8940) Avail: CASI HC A10/MF A03

This research and development program comprised two efforts: the development of guidelines for the design of automated systems, with particular emphasis on automation design that takes advantage of contextual information, and the concept-level design of a crew aiding system, the Terminal Area Navigation Decision Aiding Mediator (TANDAM). This concept outlines a system capable of organizing navigation and communication information and assisting the crew in executing the operations required in descent and approach. In service of this endeavor, problem definition activities were conducted that identified terminal area navigation and operational familiarization exercises addressing the terminal area navigation problem. Both airborne and ground-based (ATC) elements of aircraft control were extensively researched. The TANDAM system concept was then specified, and the crew interface and associated systems described. Additionally, three descent and approach scenarios were devised in order to illustrate the principal functions of the TANDAM system concept in relation to the crew, the aircraft, and ATC. A plan for the evaluation of the TANDAM system was established. The guidelines were developed based on reviews of relevant literature, and on experience gained in the design effort. Author

SAR IMAGE REGISTRATION IN ABSOLUTE COORDINATES USING GPS CARRIER PHASE POSITION AND VELOCITY INFORMATION
S. Burgett and M. Meindl 1994 5 p Presented at the International Symposium on Kinematic Systems in Geodesy, Geomatics, and Navigation, Banff, Alberta, 30 Aug. - 2 Sep. 1994
(Contract DE-AC04-94AL-85000)
(DE94-018738; SAND-94-1417C; CONF-9408163-1) Avail: CASI HC A01/MF A01

It is useful in a variety of military and commercial application to accurately register the position of synthetic aperture radar (SAR) imagery in absolute coordinates. The two basic SAR measurements, range and Doppler, can be used to solve for the position of the SAR image. Imprecise knowledge of the SAR collection platform's position and velocity vectors introduce errors in the range and Doppler measurements and can cause the apparent location of the SAR image on the ground to be in error by tens of meters. Recent advances in carrier phase GPS techniques can provide an accurate description of the collection vehicle's trajectory during the image formation process. In this paper, highly accurate carrier phase GPS trajectory information is used in conjunction with SAR imagery to demonstrate a technique for accurate registration of SAR images in WGS-84 coordinates. Flight test data will be presented that demonstrates SAR image registration errors of less than 4 meters. DOE

THE GPS BURST DETECTOR W-SENSOR
Dennis D. McCrady (ITT Aerospace/Communications Div., Clifton, NJ.) and Paul Phipps 1994 10 p Presented at the Ion-GPS 1994, Salt Lake City, UT,21 Sep. 1994
(Contract DE-AC04-94AL-85000)
(DE94-017406; SAND-94-2130C; CONF-9409185-1) Avail: CASI HC A02/MF A01

The NAVSTAR satellites have two missions: navigation and nuclear detonation detection. The main objective of this paper is to describe one of the key elements of the Nuclear Detonation Detection System (NDS), the Burst Detector W-Sensor (BDW) that was developed for the Air Force Space and Missile Systems Center, its mission on GPS Block IIR, and how it utilizes GPS timing signals to precisely locate nuclear detonations (NUDET). The paper will also cover the interface to the Burst Detector Processor (BDP) which links the BDW to the ground station where the BDW is controlled and where data from multiple satellites are processed to determine the location of the NUDET. The Block IIR BDW is the culmination of a development program that has produced a state-of-the-art, space qualified digital receiver/processor that dissipates only 30 Watts, weighs 57 lbs, and has a 12 in. x 14.2 in. x 7.16 in. footprint. The paper will highlight several of the key multilayer printed circuit cards without which the required power, weight, size, and radiation requirements could not have been met. In addition, key functions of the system software will be covered. The paper will be concluded with a discussion of the high speed digital signal processing and algorithm used to determine the time-of-arrival (TOA) of the electromagnetic pulse (EMP) from the NUDET. EVOLUTION OF GROUND LINE OF SIGHT DATA FIELD COLLECTION TECHNIQUES
J. R. Ackeret, L. A. Fatale, J. A. Messmore, and J. C. Walker Sep. 1994 12 p
(AD-A285062; USATEC-R-240) Avail: CASI HC A03/MF A01

Consideration of Line-of-Sight (LOS) conditions has always been an essential aspect of the battlefield. Knowledge of the surrounding terrain and its corresponding elevation has even more implications today in the modern Army. To date, the Defense Mapping Agency's (DMA) Digital Terrain Elevation Data (DTED) Level 1 database, an elevation matrix with 3 arc second or approximately 100-meter post spacing, has been used by most military and DOD users when elevation data was required for modeling, simulations or other applications. Recent advances in weapon systems and combat simulators has brought into question the adequacy of DTED Level 1 for terrain appreciation and threat prediction applications, especially LOS. Consequently, the need for higher resolution terrain data (e.g, greater than 30 meter post spacing) and the ability of differing resolutions of DTED to accurately predict LOS conditions is of great interest to the Army's community. AN EVALUATION OF AUTOMATIC TERMINAL INFORMATION SERVICE (ATIS) FLIGHT DECK DISPLAY PRESENTATION OPTIONS Technical Report, period ending Dec. 1992
Albert Rehmann Mar. 1994 62 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A280100; DOT/FAA/CT-TN93/25) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This document describes the first of three studies relating to human factors aspects in the flight deck display of Automatic Terminal Information Service (ATIS). This research is being conducted by the Federal Aviation Administration (FAA) Technical Center. The first part-task study examined basic format design variables. Its purpose was to begin addressing flight deck design issues pertinent to the design of the tower ATIS workstation and, collect data relevant to standard and certification groups within the FAA. Future studies in an FAA Technical Center high-fidelity mock-up and various aircraft simulators will examine full mission issues, such as procedures, equipment mechanization, and automation. Avionics data link human factors, Automatic Terminal Information Service (ATIS), Aircraft Communications Addressing and Reporting System (ACARS). DTIC

MINIMA REDUCTION SIMULATION TEST RESULTS
Barry Billmann, Edward Pugacz, and Carl Everberg Jul. 1994 73 p
(AD-A285626; DOT/FAA/CT-TN92/47) Avail: CASI HC A04/MF A01

This report presents the results of tests conducted in a Beech-200 (B-200) simulator located at the Beech Learning Center in Wichita, Kansas, and operated by Flight-Safety International (FSI). The testing was conducted to examine the feasibility of reducing approach minimums below Category I by utilizing a highly accurate navigation signal, such as the Microwave Landing System (MLS), when standard Category II approach and runway lighting are not available. Results are presented which indicate that properly trained crews using flight director-equipped aircraft can operate to lower approach minima than standard Category I without full Category II approach and runway lighting. Performance in the visual segment and touchdown performance is shown to be equivalent regardless of the availability of touchdown zone or runway centerline lighting. The benefits of a Category II approach lighting system (ALSF-2) are mitigated by the fact that when the aircraft breaks out of weather at the lower decision heights (DH's), i.e., 150 feet above ground level (AGL), most of the approach light system is already behind the aircraft. Recommendations are made for further testing in actual aircraft. DTIC

ASSESSMENT OF A NON-DEDICATED GPS RECEIVER SYSTEM FOR PRECISE AIRBORNE ATTITUDE DETERMINATION
M. E. Cannon (Calgary Univ., Alberta.), H. Sun, T. E. Owen, and M. A. Meindl 1994 10 p Presented at the Ion-GPS 1994, Salt Lake City, UT, 21 Sep. 1994
(Contract DE-AC04-94AL-85000)
(DE94-019309; SAND-94-1136C; CONF-9409185-2) Avail: CASI HC A02/MF A01

The use of a non-dedicated GPS receiver system for attitude determination was assessed in airborne mode through a test conducted at Sandia National Laboratories. Four independent NovAtel GPSCard(trademark) receivers were installed in Sandia's Twin Engine Otter with two antennas mounted on the fuselage and two on the wing tips at separations of 6 to 18 m. A strapdown INS (Inertial Navigation System) was also on board the aircraft in order to provide an independent attitude reference at rates between 4 and 10 Hz. During the multi-day test, GPS measurements were recorded between 1 and 10 Hz. Carrier phase measurements were post-processed using a double difference approach developed at The University of Calgary in which integer ambiguities were resolved in seconds using the known antenna separations as constraints. The tracking capability of the system is demonstrated under dynamics consisting of roll and pitch angles up to 45 and 12 degrees, respectively. Comparisons between the GPS and INS attitude angles are presented for two of the test days and show agreement at the several arcminute level. Conclusions are made with respect to system accuracy and performance in an operational airborne environment. DOE

THE DETERMINATION OF STATIC AND TIME VARYING DIPOLE SOURCE. SENSOR GEOMETRY DURING SEA TRIALS USING DIFFERENTIAL GLOBAL POSITIONING SYSTEM
J. Vrbancich, A. Donohoo, L. Scott, S. Turnbull, and M. Andreaus May 1993 37 p
(MRL-TN-631; AR-008-226) Copyright Avail: Issuing Activity (DSTO Materials Research Lab., PO Box 50, Ascot Vale, Victoria 3032, Australia)

Global positioning system (GPS) navigational equipment is used in differential mode to determine the time varying geometry of a boat attached to a submerged dipole source and a sensor positioned on the seafloor which is marked by a surface buoy. The requirement is to track the position of the source relative to the sensor on the seabed in sea depths less than 40 m in the vicinity of Sydney Harbor. A differential GPS (DGPS) system is formed from two or three low cost navigational units, one of which is located at a surveyed reference site and the other is located onboard the vessel. A third unit may be temporarily located at the sea surface above the sensor positioned on the seafloor. The differential system relies on software developed to apply the GPS correction obtained from the reference station to the remote stations after the geographical coordinates have been recorded. Static DGPS measurements using a 7 km baseline between remote and reference datums gave a position accuracy limited by the resolution of the GPS receiver. As a test for kinematic DGPS, the positional accuracy of the moving vessel was checked against the position coordinates derived from the laser tracking facility of the Shark Point Degaussing Range, Sydney Harbor. The agreement was usually found to be better than about 5 m, typical +/- 2 m. DGPS also enabled accurate submarine tracking at periscope depth by interfacing the submarine UHF antenna to the GPS receiver. A discussion of operational issues in the use of DGPS is also included. A REAL-TIME ALGORITHM FOR INTEGRATING DIFFERENTIAL SATELLITE AND INERTIAL NAVIGATION INFORMATION DURING HELICOPTER APPROACH M.S. Thesis
Ty Hoang Apr. 1994 67 p
(Contract NCC2-775)
(NASA-CR-197409; NAS 1.26:197409) Avail: CASI HC A04/MF A01

A real-time, high-rate precision navigation Kalman filter algorithm is developed and analyzed. This Navigation algorithm blends various navigation data collected during terminal area approach of an instrumented helicopter. Navigation data collected include helicopter position and velocity from a global position system in differential mode (DGPS) as well as helicopter velocity and attitude from an inertial navigation system (INS). The goal of the Navigation algorithm is to increase the DGPS accuracy while producing navigational data at the 64 Hertz INS update rate. It is important to note that while the data was post flight processed, the Navigation algorithm was designed for real-time analysis. The design of the Navigation algorithm resulted in a nine-state Kalman filter. The Kalman filter's state matrix contains position, velocity, and velocity bias components. The filter updates positional readings with DGPS position, INS velocity, and velocity bias information. In addition, the filter incorporates a sporadic data rejection scheme. This relatively simple model met and exceeded the ten meter absolute positional requirement. The Navigation algorithm results were compared with truth data derived from a laser tracker. The helicopter flight profile included terminal glideslope angles of 3, 6, and 9 degrees. Two flight segments extracted during each terminal approach were used to evaluate the Navigation algorithm. The first segment recorded small dynamic maneuver in the lateral plane while motion in the vertical plane was recorded by the second segment. The longitudinal, lateral, and vertical averaged positional accuracies for all three glideslope approaches are as follows (mean plus or minus two standard deviations in meters): longitudinal (-0.03 plus or minus 1.41), lateral (-1.29 plus or minus 2.36), and vertical (-0.76 plus or minus 2.05). (Contract NAS9-18000)
(NASA-CR-197290; NAS 1.26:197290) Avail: CASI HC A02/MF A01

This report summarizes the experience of the authors in managing, designing, and implementing an object-oriented applications framework for orbital navigation analysis for the Flight Design and Dynamics Department of the Rockwell Space Operations Company in Houston, in support of the Mission Operations Directorate of NASA's Johnson Space Center. The 8 person year project spanned 1.5 years and produced 30,000 lines of C++ code, replacing 150,000 lines of Fortran/C. We believe that our experience is important because it represents a 'second project' experience and generated real production-quality code - it was not a pilot. The project successfully demonstrated the use of 'continuous development' or rapid prototyping techniques. Use of formal methods and executable models contributed to the quality of the code. Keys to the success of the project were a strong architectural vision and highly skilled workers. This report focuses on process and methodology, and not on a detailed design description of the product. But the true importance of the object-oriented paradigm is its liberation of the developer to focus on the problem rather than the means used to solve the problem. Author

VARIATIONS OBSERVED IN THE AC GENERATOR SIGNAL PERIOD OF A SEA KING HELICOPTER

D. M. Blunt Jun. 1994 25 p
(AD-A284280; DSTO-GD-0004; DODA-AR-008-545) Avail: CASI HC A03/MF A01

The AC generator in the Sea King helicopter can be used as a convenient source of a tachometer signal from the main rotor gearbox, thus enabling synchronous vibration signal averages to be calculated for every shaft in the gearbox. The signal averaging software developed by ARL determines the shaft speeds by measuring the tachometer signal period. Variations in the tachometer signal period not caused by changes in gearbox speed will affect the accuracy of the vibration signal averages. An examination has been made of the AC generator signal of a Sea King helicopter recorded on a Bruel & Kjaer 4 channel FM tape recorder (model 7003). The results show that the signal averaging software measures short term period variations (from one period to the next) in the AC generator signal of up toapp roximately 2% of the mean period. It was found that while most of this variation probably arises from noise present in the recording environment, a considerable proportion comes from noise introduced through the tape recording and filtering processes. BOMBER FORCE 2000: OPERATIONAL CONCEPTS FOR LONG-RANGE COMBAT AIRCRAFT Final Report

Jeffrey K. Beene 8 Feb. 1994 61 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A279378) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This research paper seeks to synthesize analyses of air power theory and doctrine, historical insights from major operations, current thinking, and the emerging strategic environment to detail concepts for improved planning and execution of future air operations. These operations would fully integrate bombers as long-range combat aviation assets. The search for a type of aircraft to fit the doctrine derived from early interpretations of air power theory has hindered development of bomber potential. The use of atomic weapons at the end of World War 2 and the ensuing Cold War further obscured understanding of bombers, their real contribution hinging on viewing them as long-range combat aircraft. Today, the bomber is not obsolete, but its traditional nuclear paradigm is. The emergence of regional threats combined with a shrinking defense establishment and the global compression of time and space demand full integration of bomber aircraft into the U.S. air power arsenal. These aircraft provide a theater commander with a unique capability to respond rapidly across the spectrum of conflict from a peacetime show of force to major nuclear or nonnuclear conflict. However, for the operational commander to employ bomber assets effectively requires a full recognition of bomber attributes and a thorough understanding of their capabilities. DTIC

NAVAL AVIATION: F-14 UPGRADES ARE NOT ADEQUATELY JUSTIFIED. REPORT TO CONGRESSIONAL COMMITTEES

Oct. 1994 12 p
(AD-A286338; GAO/NSIAD-95-12; B-257718) Avail: CASI HC A03/MF A01; GAO, PO Box 6015, Gaithersburg, MD 20884-6015 HC

The implications of the Navy's decision to spend about $2.5 billion between fiscal years 1994 and 2003 for a limited ground attack upgrade and other modifications to about 200 F-14 Tomcat fighters was evaluated. This upgrade was included to add limited ground attack capability and other improvements to 210 F-14 Tomcat fighter aircraft. According to the Navy, the ground attack capabilities were required to partially compensate for the loss in combat capabilities during the period starting in 1997, when all of its A-6E Intruder attack aircraft are scheduled to be retired, to the turn of the century when the F/A-18E/F, the next generation strike fighter, is scheduled to arrive. Although the Navy justified F-14 attack upgrades as necessary to replace some capability that will be lost when it retires all A-6E attack aircraft by fiscal year 1998, planned upgrades will not include an air-to-ground radar for precision ground mapping that would permit crews to locate, identify, and attack targets in adverse weather and poor visibility. In addition, no F-14 will be able to launch current or planned precision munitions or stand-off weapons, except for LGBS. Upgraded F-14's generally have greater range than the F/A-18C and could possibly reach targets beyond the Hornet's range. However, this capability may not be needed with the Navy's shift to a littoral warfare strategy. If greater range is needed, the Navy's Tomahawk cruise missile can attack targets up to a range of about 700 miles, and Air Force bombers have even greater range. Both supplement and complement carrier aviation in striking deep within enemy territory. The Navy has not made a compelling case to proceed with its $2.5 billion plan. DTIC

PARALLEL CALCULATION OF SENSITIVITY DERIVATIVES FOR AIRCRAFT DESIGN USING AUTOMATIC DIFFERENTIATION

C. H. Bischof (Argonne National Lab., IL.), T. L. Knauff, Jr. (Argonne National Lab., IL.), L. L. Green, and K. J. Haigler Jan. 1994 24 p Presented at the 5th AIAA/NASA/USAF/ISSMO Symposium on Multidisciplinary Analysis and Optimization Conference, Panama City, FL, 7-9 Sep. 1994
(Contract W-31-109-eng-38)
(NASA-TM-110103; NAS 1.15:110103; DE94-016894; ANL/MCS/CP-82870; CONF-9409187-1) Avail: CASI HC A03/MF A01

Realistic multidisciplinary design optimization (MDO) of advanced aircraft using state-of-the-art computers is an extremely challenging problem from both the physical modelling and computer science points of view. In order to produce an efficient aircraft design, many trade-offs must be made among the various physical design variables. Similarly, in order to produce an efficient design scheme, many trade-offs must be made among the various MDO implementation options. In this paper, we examine the effects of vectorization and coarse-grained parallelization on the SD calculation using a representative example taken from a transonic transport design problem. DOE

SIMULATION OF ROTOR BLADE ELEMENT TURBULENCE

R. E. McFarland and Ken Duisenberg (Systems Consultants, Inc., Falls Church, VA.) Jan. 1995 17 p

(RTOP 505-64-29)

(NASA-TM-108862; A-95028; NAS 1.15:108862) Avail: CASI HC A03/MF A01

A piloted, motion-based simulation of Sikorsky's Black Hawk helicopter was used as a platform for the investigation of rotorcraft responses to vertical turbulence. By using an innovative temporal and geometrical distribution algorithm that preserved the statistical characteristics of the turbulence over the rotor disc, stochastic velocity components were applied at each of twenty blade-element stations. This model was implemented on NASA Ames' Vertical Motion Simulator (VMS), and ten test pilots were used to establish that the model created realistic cues. The objectives of this research included the establishment of a simulation-technology basis for future investigation into real-time turbulence modeling. This goal was achieved; our extensive additions to the rotor model added less than a 10 percent computational overhead. Using a VAX 9000 computer the entire simulation required a cycle time of less than 12 msec. Pilot opinion during this simulation was generally quite favorable. For low speed flight the consensus was that SORBET (acronym for title) was better than the conventional body-fixed model, which was used for comparison purposes, and was determined to be too violent (like a washboard). For high speed flight the pilots could not identify differences between these models. These opinions were something of a surprise because only the vertical turbulence component on the rotor system was implemented in SORBET. Because of the finite-element distribution of the inputs, induced outputs were observed in all translational and rotational axes. Extensive post-simulation spectral analyses of the SORBET model suggest that proper rotorcraft turbulence modeling requires that vertical atmospheric disturbances not be superimposed at the vehicle center of gravity but, rather, be input into the rotor system, where the rotor-to-body transfer function severely attenuates high frequency rotorcraft responses. EFFECT OF ATMOSPHERIC PRESSURE ON MEASURED AIRCRAFT NOISE LEVELS

R. C. Payne Mar. 1994 58 p

(PB95-130423; NPL-RSA(EXT)0048) Copyright Avail: Issuing Activity (National Technical Information Service (NTIS))

Noise certification of subsonic jet airplanes, heavy propeller-driven airplane and helicopters is carried out using the procedures described in the International Civil Aviation Organization (ICAO) document Annex 16. Measured noise levels are corrected to reference atmospheric conditions to allow for differences in air attenuation resulting from variations in ambient temperature and relative humidity. The attenuation is calculated using the Society of Automotive Engineers standard ARP 866A. The procedure does not include the effect of ambient atmospheric pressure. The report discusses the influence of atmospheric pressure on the attenuation of sound transmitted to the ground during noise certification tests carried out using airfields at altitude. ARP 866A and three alternative procedures that include the effect of atmospheric pressure are assessed, and calculations are made of air attenuation rates based on reference atmospheric pressure and pressures that are representative of those that occur at airfields located at altitudes of up to 10000 feet (3048 m). Comparison of these attenuation rates shows differences that are dependent on temperature, relative humidity, frequency and altitude. The effect of these differences on EPNL evaluation is difficult to assess as it is dependent not only on meteorological conditions, but also on spectral shape and propagation distance. NTIS

EFFECT OF JUNCTURE FILLETS ON DOUBLE-DELTA WINGS UNDERGOING SIDESLIP AT HIGH ANGLES OF ATTACK M.S. Thesis

Wen-Huan Chang Sep. 1994 216 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(AD-A286165) Avail: CASI HC A10

A flow visualization study of the vortical flow over a baseline double-delta wing model and a diamond-fillet double-delta wing model both with sharp leading edges was conducted in the Naval Postgraduate School water tunnel using the dye-injection technique. The main focus of this study was to observe the effect of juncture fillet on the vortex core trajectory, and vortex burst location on the wing surface at high angles of attack with sideslip angles. The results indicate that the strake vortex burst point moves upstream with increasing angle of attack at zero sideslip angle; but at constant angle of attack the windward side strake vortex burst location moves upstream and inboard while the leeward side vortex burst point moves downstream and outboard with increasing sideslip angle. Comparison of test results between the baseline model and the diamond-fillet model indicates a clear delay for the latter model in terms of both vortex core trajectory and breakdown location at high angles of attack with and without sideslip angle. The vortex breakdown data for the diamond-fillet model implies lift augmentation during sideslip motion, thus supporting the concept of flow control using fillets. DTIC

INVESTIGATION OF FLIGHT DATA RECORDER FIRE TEST REQUIREMENTS
Lawrence J. Curran, Jr. Oct. 1994 27 p
(AD-A285832; DOT/FAA/CT-TN94/23) Avail: CASI HC A03/MF A01

This report evaluates fire test methodologies for aircraft flight data and cockpit voice recorders. The current fire test requirement consists of a 30-minute exposure to a propane burner calibrated to the heating conditions created by a jet fuel fire. A comparison was made of the internal temperature of flight recorder models subjected to the propane burner standard and a jet fuel fire. The internal temperature was approximately 40 percent higher during the fuel fire tests which were 6-8 minutes in duration. Although the fuel fire duration was limited, it appears that a 60-minute propane burner test exposure is a feasible and conservative means of evaluating the thermal resistance of a flight recorder subjected to a 30-minute fuel fire. An additional fire test condition (500 F/10 hours) has been proposed to simulate a smoldering fire which may persist for a long period of time at a remote site. A state-of-the-art magnetic tape of the cockpit voice recorder was subjected to this condition in an oven and failed the test, demonstrating the severity of this exposure environment. DTIC

ADVANCED PACKAGING CONCEPTS FOR DIGITAL AVIONICS [LES TECHNIQUES AVANCEES DE MISE SOUS BOITIER]
Oct. 1994 287 p In ENGLISH and FRENCH Symposium held in San Diego, CA, 6-9 Jun. 1994
(AGARD-CP-562; ISBN-92-836-0004-5) Copyright Avail: CASI HC A13/MF A03

A critical impediment to significantly improving the performance of digital airborne electronics or avionics is the limitation posed by current electronics packaging concepts. This symposium brought together experts from seemingly diverse, but interlocking disciplines ranging from logisticians to digital designers to mechanical engineers to establish the current baseline in digital packaging, failure modes of the electronics and support problems. Trends in both supportability and processing were described for early 21st century application. Along with the projections of asymptotic increase in signal, image and data processing, dramatic increases in thermal densities, chip interconnects, correctors and backplane traffic were described. For individual titles, see N95-20632 through N95-20659.

THE IMPACT OF ADVANCED PACKAGING TECHNOLOGY ON MODULAR AVIONICS ARCHITECTURES
Reed Morgan and John Ostgaard *In* AGARD, Advanced Packaging Concepts for Digital Avionics Oct. 1994 12 p (For primary document see N95-20631 06-06)
Copyright Avail: CASI HC A03/MF A03

This paper explores how advances in digital packaging will impact network requirements at the system level. Two main issues connected with modular digital packaging for avionics were investigated: (1) Can conventional electrical designs continue to handle the information network speed and wirability requirements needed at the backplane to efficiently utilize advanced modular data and signal processors? (2) Considering projected network requirements for future sensors, displays, etc., (which are made possible because of digital packaging advances), what type of system architecture will be needed? The paper concludes that: (1) Beyond the module (PCB) interface, a new type of backplane implementation will eventually be needed to support the flexibility and growth needs of modular processing. Several new approaches other than a passive electrical backplane could be employed; however, a switched, photonic-based approach is proposed for information distribution between digital processing modules as well as for interconnection between peripherals. Digital packaging advances will result in I/O speeds of about 2 Gigabits/sec, and (2) advanced integrated RF and EO sensors and display technologies will require network data rates in the range of 2 Gigabits/sec in order to communicate in real time with the high speed signal and graphics processor modules in the common integrated processor racks. Many of these 'peripheral' functions will require virtual point-point links because continuous, streaming data in involved. This resulting system architecture recommended is a switched optical network which interconnects sources and sinks of information to the modular processing assets, as well as providing a network for intermodule intercommunication within the rack. Issues of protocol control of this network remain. Further, several advances in photonic packaging and connectors will be required to make this new architectural approach a reality. Although photonics offers the best long-range solution, significant technology difficulties must be overcome. Author

The objective of the 'Advanced SEM-E Packaging' is 'to identify existing SEM-E and modular avionics characteristics; delineate where they are not defined; and document consensual requirements and guidance for military and commercial applications to provide a framework for open systems architecture implementation'. SHARP has teamed with the Air Force Modular Avionics Systems Architecture (MASA) Program to bridge Industry and government agencies in defining and documenting Standard Electronic Module (SEM) format E advanced packaging requirements. The baseline for the working group has been identified, but SHARP and MASA are soliciting participation and input from industry, other agencies, and NATO. Author

Modular avionics is one of the major concepts to be applied to future avionics systems with the objective of cost (LCC - Life Cycle Cost) containment and improvement of operational performance. The objectives associated with such a concept are numerous: improvement of reliability, standardization, interchangeability, interoperability, etc. To obtain these objectives it is necessary to define characteristics standards for modules (LRM - Line Replaceable Module). The definition of these standards for LRM has a direct impact on the modules and their integration. The choice of the best concept takes place through a careful study of the repercussions of each solution on all levels (racks, bays and platforms), in all the technical fields (thermal, electric, mechanical, electromagnetic protection, connectors). This article presents the results of a parametric platform/system-avionics study and more particularly the possible choices for orientation of the platform on aircraft or helicopters. The method used defines the platform constraints to be parameterized and their interactions. The effects are initially integrated in a model representative of standard missions. Thus the results, field by field, show the importance of the effects of constraints on the platform system. Finally, a process of complete dimensioning of the platform, including the functional reliability aspects leads to the synthesis. This allows both a quantitative and qualitative check of the robustness of the compromises carried out. In conclusion, the control of the platform/avionics-system compromise, by an approach of simultaneous engineering, makes it possible to justify a solution of conditioning of the modular avionics in the optics of a future system. The main requirements for modular avionics have a strong influence on the Packaging solutions for the Line Replaceable Modules (LRM's) and the rack. Packaging is here including: mechanical concepts, cooling, power supplies, interconnections and electromagnetic compatibility. To define the packaging solutions for the next generation of avionics, a parametric study, FASTPACK, has been performed at the platform and avionics levels. The present paper deals with the avionics part and shows how the FASTPACK parametric study has been conducted in order to define a synthesis in each domain, used to derive Packaging concepts. The main results include the choice of a LRM format, called FAST, a distributed power supply network within the rack, conduction and liquid flow through cooling, shielding on the rack against external electromagnetic threats and shielding on the LRM for rack internal interferences and, finally, the first definition of the LRM connector. The Navy's Advanced Avionics Subsystem Technology (AAST) Fault Tolerant program is clarifying the Navy's fault tolerant avionics specifications methods and acceptance tests. The goal of the program will be to clarify the Specification and Statement of Work language needed in future procurements and to demonstrate fault tolerant validation tools on the avionics design. A set of tool features will then be developed that spans the needs of fault tolerant computer system design from early concept studies to full scale production and operational support, both hardware and software. The paper will give an overview of the AAST Fault Tolerant Demonstration and focus on two tools that are being used in the demonstration: FERRARI - a software fault injector that will be used to validate the fault tolerance of the Common Integrated Processor (CIP), the F-22 Mission Processor, and GRIND - a concept evaluation tool that will be used to evaluate the overall CIP architecture. The Intelligent MCM Analyzer (IMCMA) is a software tool which allows the designer to concurrently assess the reliability of an MCM design based on operational parameters. Traditionally, this type of assessment takes days to accomplish and is performed after the design phase. The Intelligent MCM Analyzer does not require the designer to be a thermal/reliability expert and gives an assessment in minutes depending on the complexity of the design and the speed of the computer. IMCMA assists the designer in achieving a robust design which will improve both quality and reliability. The software uses object-oriented data representation, a blackboard architecture and heuristic expertise to perform lower level reasoning associated with finite element thermal analysis techniques that are normally very tedious and labor intensive. A test case will be presented comparing results from IMCMA with the results from a general purpose finite element code. The ultimate payoff will be the manufacturers' ability to build higher quality, higher reliability MCM's at a lower cost. Author

Texas Instruments Incorporated (TI) developed the URDA processor design under contract with the U.S. Air Force Wright Laboratory and the U.S. Army Night Vision and Electro-Sensors Directorate. TI's approach couples advanced packaging solutions with advanced integrated circuit (IC) technology to provide a high-performance (200 MIPS/800 MFLOPS) modular avionics processor module for a wide range of avionics applications. TI's processor design integrates two Ada-programmable, URDA basic processor modules (BPM's) with a JIAWG-compatible PiBus and TMBus on a single F-22 common integrated processor-compatible form-factor SEM-E avionics card. A separate, high-speed (25-MWord/second 32-bit word) input/output bus is provided for sensor data. Each BPM provides a peak throughput of 100 MIPS scalar concurrent with 400-MFLOPS vector processing in a removable multichip module (MCM) mounted to a liquid-flowthrough (LFT) core and interfacing to a processor interface module printed wiring board (PWB). Commercial RISC technology coupled with TI's advanced bipolar complementary metal oxide semiconductor (BiCMOS) application specific integrated circuit (ASIC) and silicon-on-silicon packaging technologies are used to achieve the high performance in a miniaturized package. A Mips R4000-family reduced instruction set computer (RISC) processor and a TI 100-MHz BiCMOS vector coprocessor (VCP) ASIC provide, respectively, the 100 MIPS of a scalar processor throughput and 400 MFLOPS of vector processing throughput for each BPM. The TI Aladdim ASIC chipset was developed on the TI Aladdin Program under contract with the U.S. Army Communications and Electronics Command and was sponsored by the Advanced Research Projects Agency with technical direction from the U.S. Army Night Vision and Electro-Sensors Directorate. The MAMA (Mixed Arithmetic, Multiprocessing Array) module is being developed to evaluate new packaging technologies and processing paradigms for advanced military processing systems. The architecture supports a tight mix of signal, data,and I/O processing at GFLOP throughput rates. It is fabricated using only commercial-on-the-sehlf (COTS) chips and will provide a high level of durability. Its attributes are largely the result of two new interconnection and packaging technologies. Chip-in-board packaging is used to reduce local x-y communication delays and solder joints, while significantly improving board-level packaging density. A unique 3-D interconnection technology called a cross-over cell has been developed to reduce board-to-board communication delays, drive power, glue logic, and card-edge pin-outs. These technologies enable true 3-D structures that are form, fit and connector compatible with conventional line-replacable modules. The module's design rational, packaging technology, and basic architecture will be presented in this paper. Author

Production of microelectronic devices encapsulated in solid, molded plastic packages has rapidly increased since the early 1980's. Today, millions of plastic-encapsulated devices are produced daily. On the other hand, only a few million hermetic (cavity) packages are produced per year. Reasons for the increased use of plastic-encapsulated packages include cost, availability, size, weight, quality, and reliability. Markets taking advantage of this technology range from computers and telecommunications to automotive uses. Yet, several industries, the military in particular, will not accept such devices. One reason for this reluctance to use the best available commercial parts is a perceived risk of poor reliability, derived from antiquated military specifications, standards, and handbooks; other common justifications cite differing environments; inadequate screens; inadequate test data, and required government audits of suppliers' processes. This paper describes failure mechanisms associated with plastic encapsulation and their elimination. It provides data indicating the relative reliability of cavity and solid-encapsulated packaging, and presents possible approaches to assuring quality and reliability in the procuring and applying this successful commercial technology. There are already several Multi Chip Module (MCM) technologies suitable for avionics applications, and new variations and updates are continually being added. The optimum technology choice for each avionics application will depend on many factors, including the electrical and thermal requirements, the operating environment, size, weight, quantity, cost, etc. This paper will compare the attributes of the various MCM technologies, both at present and future trends, including 3D assembly/packaging and the use of active substrates for MCM-D's. The means of mounting MCM's and interconnecting them into the system using electrical or optical interconnection will also be compared. Some of the methods used to remove very high levels of power dissipation will also be discussed, in relation to the different technologies. The requirements of electronic modules in different parts of avionics systems may be sufficiently different that alternative solutions are optimal for the various parts. The paper will briefly review the range of requirements across military (and comparable civil) avionics systems and, by considering the technology options, indicate how the optimum choice can be decided, both for the MCM's themselves and for the means of interconnection between MCM's and from MCM's to other parts of the system. The objective of the 'Advanced SEM Processes' effort is to simplify the development and qualification processes and reduce the related process times and costs from the current way of doing business. Advanced technology developments and qualifications typically are completed in three to five years from conception. The Standard Hardware Acquisition and Reliability Program (SHARP) is working in conjunction with the Advanced Research Project Agency (ARPA) Application Specific Electronic Modules (ASEM) effort, Raytheon and the Electronics Manufacturing Producibility Facility (EMPF) Manufacturing Technology efforts to define new processes for development and qualification that leverage commercial and military technology in applying 'MultiChip Modules' (MCM's) to Standard Electronic Module format E (SEM-E) packaging. These processes are anticipated to have applicability to the development and qualification of SEM-E packaging, using multiple state of the art technologies in addition to MCM's. The primary objective is to reduce the current cycle time from three - five years to twelve months and costs from $500,000 - $1,000,000 to $100,00 - $250,000, therefore providing a baseline for standardizing electronics hardware acquisition processes into the twenty first century and beyond. Multichip Module (MCM) packaging/interconnect technologies have seen increased emphasis from both the commercial and military communities as a means of increasing capability and performance while providing a vehicle for reducing cost, power and weight of the end item electronic application. This is accomplished through three basic Multichip module technologies, MCM-L that are laminates, MCM-C that are ceramic type substrates and MCM-D that are deposited substrates (e.g., polymer dielectric with thin film metals). Three types of interconnect structures are also used with these substrates and include, wire bond, Tape Automated Bonds (TAB) and flip chip ball bonds. Application, cost, producibility and reliability are the drivers that will determine which MCM technology will best fit a respective need or requirement. With all the benefits and technologies cited, it would be expected that the use of, or the planned use of, MCM's would be more extensive in both military and commercial applications. However, two significant roadblocks exist to implementation of these new technologies: the absence of reliability data and a single national standard for the procurement of reliable/quality MCM's. To address the preceding issues, the Reliability Technology to Achieve Insertion of Advanced Packaging (RELTECH) program has been established. This program, which began in May 1992, has endeavored to evaluate a cross section of MCM technologies covering all classes of MCM's previously cited. NASA and the Tri-Services (Air Force Rome Laboratory, Naval Surface Warfare Center, Crane IN and Army Research Laboratory) have teamed together with sponsorship from ARPA to evaluate the performance, reliability and producibility of MCM's for both military and commercial usage. This is done in close cooperation with our industry partners whose support is critical to the goals of the program. Several tasks are being performed by the RELTECH program and data from this effort, in conjunction with information from our industry partners as well as discussions with industry organizations (IPC, EIA, ISHM, etc.) are being used to develop the qualification and screening requirements for MCM's. Specific tasks being performed by the RELTECH program include technical assessments, product evaluations, reliability modeling, environmental testing, and failure analysis. This paper will describe the various tasks associated with the RELTECH program, status, progress and a description of the national dual use specification being developed for MCM technologies. Author

ASSURING KNOWN GOOD DIE (KGD) FOR RELIABLE, COST EFFECTIVE MCMs c33
Daniel E. Daskiewich *In* AGARD, Advanced Packaging Concepts for Digital Avionics Oct. 1994 7 p (For primary document see N95-20631 06-06)
Copyright Avail: CASI HC A02/MF A03

A key requirement for achieving high yield multichip modules (MCM's) is assuring that the individual dice are known good devices (KGD). A KGD is defined as a bare die available at the same quality and reliability as the equivalent single chip packaged parts. Integrated circuits (IC's) that are Known Good will function over a specified temperature range, are compatible with the MCM approach utilized, and contain no short-term or long-term reliability hazards. The application of reliability and testability techniques at all levels of MCM development, particularly at the chip level, will maximize MCM yield. Today's testing and qualification requirements, defined by MIL-STD-883 Methods 5008 and 2010, are not capable of assuring KGD as defined above. The development of cost effective requirements for achieving 99.9 percent yields poses a challenge which requires new and novel approaches and better methods for bare die testing, wafer level burn-in, tape automated bonding (TAB), temporary packaging, at-speed device testing at the wafer, die, and MCM level. Also of great importance are the methods for built-in self test (BIST), built-in test (BIT), and boundary scan. New standards in very large scale integration (VLSI) device testing must be developed in order for MCM's to be reliable and economical. Rome Laboratory (RL) has funded a program to address and develop these requirements. The objectives of the RL program are to: research and evaluate current and proposed burn-in, electrical and interconnect test techniques for assuring known good VLSI circuits at wafer and die level; and evaluate various methods of incorporating testability features which will decrease test time and cost. In addition, MCM-level reliability and performance assessment procedures will be evaluated to determine appropriate testing concepts and procedures that will assure the procurement of reliable, cost effective MCM's for DOD/NASA applications. The program consists of two phases: Phase One will be a study phase to evaluate, analyze, trade-off, and select best techniques for test and burn-in of wafers, bare die and MCM's. Phase Two will be a demonstration of a cost effective procedure for assuring high quality/reliable production of MCM's based on the KGD methods developed in Phase One. Author

The demand for engine control systems with reduced weight, size and cost, increased integration, improved reliability and higher temperature operation drives the system designer to the use of advanced hybrid assembly technologies. This paper describes the design and manufacturing development of a silicon based 'D' type multichip module, MCM, containing an active substrate of memory. This CPU module is one of the building blocks for a range of generic engine control systems. The active substrate approach potentially gives higher packing density than wafer scale due to its 3D configuration. The active substrate comprises 12 SRAM 128K x 8 bit of diffused memory arranged in groups of three. The design is organized so that a 'memory manager' ASIC selects pages of good memory from the substrate die thus obtaining the best possible yield. A single wafer contains 4 silicon hybrid substrates, each approximately 40mm sq, which will be processed before separating into discrete circuits. The MCM structure is comprised of four aluminium metallization layers with benzocyclobutene, BCB, as the dielectric. Approximately 16 other devices including a processor, the 'memory manager' ASIC, a Processor Support ASIC and EDPROM, plus resistor network chips and decoupling capacitors will be added to the silicon substrate using adhesive and wire bond interconnection. The 'memory manager' ASIC tests the RAM on power-up, reject areas of bad memory and configures the good areas such that a continuous block of functional RAM is available to the processor. The RAM is configured as a 16 bit wide with both 16 bit and 8 bit read/write accesses being supported. The total module is to be assembled in a high temperature co-fired ceramic package with 200 I/O. After test and any rework that may be necessary the package will be sealed with a Kovar lid ready for final test. Author

There has been a need for generic technologies and common approaches in design, development, and manufacturing of military and commercial products. This need is more pronounced and pressing today than ever before. With the objective to dramatically enhance avionics reliability, maintainability and availability (RM&A), an integrated, generic technology for packaging, cooling, and interconnection of high density and high performance circuits was developed. It is named High Density Monolithic Packaging (HDMP). Under the sponsorship of Wright Laboratory, a two-part complementary program (1990-1994), named Advanced Radio-Frequency Packaging/ARFP was contracted to Westinghouse. Under the ARFP program, the HDMP technology is being applied and its promising capability is being assessed for its ability to reduce the low power RF avionics life-cycle cost. Being better than half way through the program, the results and projections have been extremely promising. The technology assessment is approximately 50 percent complete and initial results have been extremely successful. Although the focus of the development effort has been on RF subsystems, the basic elements of HDMP technology have applications beyond RF/microwave subsystems. As digital processing speeds increase, RF/microwave design techniques must be applied to maintain high speed digital signal integrity. The basic elements of the HDMP technology are: low temperature co-fired ceramic (LTCC), solderless interconnects, multichip modules (MCM's), and composite heatsink materials. The key technology element, in this avionics availability enabling technology, is LTCC. LTCC material technology is a monolithic multilayered ceramic and conductor/metallization structure used as a substrate to support dense co-habitation of high density electronic circuits, their interconnections, and the electromechanical integrity of the integrated constituents. Thermal management of future avionics modules will be a critical design issue. New advances in integrated circuit technology and electronic packaging will allow the design of densely populated electronics modules with potential power dissipation levels in excess of 1.0 W/cm(exp 2). While the module power level trend will be to increase, the maximum allowable junction temperature for integrated circuits may be lowered to provide more benign thermal environment for electronics. This negates the use of conventional thermal management techniques in new avionics applications. A number of trade studies were performed to determine which cooling technique would be best suited to meet the anticipated reliability and performance requirements for the year 2005 and beyond. The approaches to module cooling technologies considered were: edge cooled conduction, immersion, and hollow core flow-through. The technology selected was the hollow core flow-through. This paper discusses the results of flow-through cooling investigations on both single-pass cold plates and SEM-E modules. Author

Due to increasing heat dissipation requirements, the need for an advanced cooling technique in current military avionics has been recognized. Immersion cooling with phase change has been demonstrated in a Format E clamshell module as an alternative. This module is capable of dissipating more than 700 Watts. From the development of the Format E clamshell module the AAS&T (Advanced Avionics Subsystems and Technology) Program has begun an effort to utilize the clamshell module in the development of a 3/4 ATR Format E Standard Avionics Enclosure utilizing immersion/change of phase cooling. The power dissipation requirement for the enclosure is 6500 Watts minimum. The cooling medium for both efforts is a Fluorinert (FS-72). The FS-72 is an environmentally safe coolant. As the need for greater heat removal and reliability increases, cooling technology must become more advanced to meet the needs of next generation aircraft. Author

MICROCHANNEL HEAT PIPE COOLING OF MODULES c34

G. Moser *In* AGARD, Advanced Packaging Concepts for Digital Avionics Oct. 1994 12 p (For primary document see N95-20631 06-06)

Copyright Avail: CASI HC A03/MF A03

The purpose of this presentation is the proposal of a novel, highly sophisticated cooling technique with a promising performance, but with a very early status of development - the microchannel heat pipe cooling. This technique can be directly adapted to the basic idea of Modular Avionics resulting on the hardware side in a modular packaging design with interchangeable modules. Due to the early status of the development and of the basic research some of the very stringent requirements for military airborne equipment are not met yet (or information is missing) like the impact of acceleration and orientation; nevertheless, the normal performance capability is highly compliant with the dramatically increasing local maximum heat densities and total maximum heat dissipations, which are forecast for future avionic applications. The presentation shall highlight the status of the development and the benefits of this technique; the latter is done by a comparison to the well established cooling methods for the module like Liquid Flow Through (LFT) and conduction cooling, in order to provide a clear impression of the cooling capabilities. Especially if the microchannel heat pipe is combined with a micro heat exchanger for the heat transfer off the module, the performance with respect to the maximum local heat density, the most challenging requirement for the future, is high in excess of the LFT method. The U.S. Navy Next Generation Computer Resources (NGCR) High Speed Data Transfer Network (HSDTN) program has chosen the IEEE Scalable Coherent Interface (SCI) as one of its baseline standards. This paper proposes to use SCI as a unified avionics network and describes SCI and extensions to it -- particularly an extension known as SCI/ Real Time (SCI/RT). Because SCI can be used in a serial configuration, such a network provides an alternative to the need for ever denser and ever more reliable backplane connectors by reducing the number and size of interconnects and, hence, the need for large numbers of pins. In addition, SCI reduces packaging problems by using a small amount of board real estate and by using distance insensitive links which can extend board to board or box to box, thus facilitating a distributed backplane approach for retrofit aircraft applications. SCI is currently being applied to both parallel and to serial implementations, to both message passing and shared memory computing paradigms, and to both electrical and optical physical layers. SCI/RT is a set of proposed enhancements, developed initially by the Canadian Navy and now being evaluated by the NGGR HSDTN and IEEE working groups, to make SCI more fault tolerant and to provide the determinism and priorities necessary to support Rate Monotonic Scheduling. Addition of these features will allow SCI to perform in a unified and seamless manner, the functions of command and control interconnect, data flow network and sensor/video network. Electrical and optical, and serial and parallel links can be intermixed for the most cost effective solution. As an added benefit, SCI has potential for use interconnecting multiple processing chips on the same board. Author

This paper presents an active matching technique for extending the data rates of electrical backplane interconnects into the gigabit per second (Gb/s) range. In the active matching technique an active bandpass amplifier is used to drive the backplane transmission lines. The gain characteristic of the amplifier is designed to be complementary to that of the transmission line and connectors using standard microwave matching techniques. This technique is suitable for use with conventional stripline and microstrip backplanes as well as newer microcoaxial cables. Using this technique, backplanes operating at serial data rates in excess of 4 Gb/s have been demonstrated and speeds of 10 Gb/s may be possible. These results suggest that electrical backplanes may be competitive with optical backplanes in speed and superior to them in cost, power consumption, and complexity. Author

An experimental study was carried out by DASA and Daimler Benz Research to demonstrate the feasibility of fiber optic technology for use in Modular Avionics. In the first step of the study an inter module communication up to 16 subscribers, with interconnection length of about 1 m was demonstrated. Backplanes being composed of multimode and monomode fibers were tested in a configuration of 4 parallel data channels, each running with 1 GBit/s. This paper will resume results of investigations as: power budget, influence of modal noise with multimode fibers, effects of feedback, as well as optical interference caused by reflections. The paper then goes on to describe the transparency for given protocols (e.g., PI-bus). A prospect of problems arising of optical interconnections of a relatively large number of subscribers and possible solutions by using in-line amplifiers (optically) are reviewed. The backplane implementation is prepared to be arranged as a serial/parallel bus or a part of a switched network. Finally, this paper will give a synopsis of optical backplane solutions. Author

The new multimode connector has been developed that will function under harsh environmental conditions. It meets the military's need for a reliable optical insert that can be integrated into existing electrical, card-edge connectors. Expanded-beam optics and micro-machined silicon sub-assemblies are employed to achieve low optical loss (less than 1 dB) under blind-mate conditions. Low-mass, floating termini and kinematic design make the ROC connector insensitive to high levels of shock and vibration. Self sealing doors protect the optical assemblies from particulate contamination and abusive handling. The connector has performed flawlessly under extensive environmental and durability testing. This paper will describe the ROC design, features, and test results. Author

The goal of this paper is to present work related to the development (study, fabrication, qualification) of a box and a bonnet cover out of composite materials intended for airborne electronic equipment on fighter aircraft. Work was undertaken with a double objective: assess mass characteristics compared to a metal case and obtain equivalent electromagnetic shielding performance. The technological step is presented: choice of materials and the processes of fabrication, mechanical and electromagnetic dimensioning. The methods of manufacture are described; they made it possible to obtain the desired characteristics. The metal composite material elements are currently being used on fighter aircraft. The ever increasing demand in technical and economical performances improvement of aircrafts has a direct incidence for avionics. Except microelectronic integration, the enclosures have a high potential of evolution. The main advantages of composite materials over metals in forming electronic enclosure are: reduction of weight (minimum 30 percent), better resistance to corrosion, improved fatigue and impact resistance, achievement of complex shapes, and low coefficient of thermal expansion. The main problems to be solved in extending the application of the use of composite materials to the field of airborne electronic equipments are to: provide adequate electromagnetic shielding, ensure survival in harsh thermal and mechanical environments, and achieve global competitivity of the final products. Different technologies have been considered: injection molding of short fibers reinforced thermoplastic for small sized equipments (V less than 21), pressure molding of graphite and glass reinforced thermosets for ATR case families, and metal matrix composites. This paper will address the main investigations that have been undertaken in France since 1986 in the first two fields covering both manufacturing and evaluation results. Author

Future avionics systems will be based on a modular architecture in which each elementary function will correspond to a line replacable module (LRM). Parametric studies, such as FASTPACK, showed that the optimal solution for the supply systems was an architecture distributed on only one level of energy transformation, i.e., a modular supply on each LRM able to deliver 50 W with 100 W directly starting from the main supply system (270 V(dc) or three-phase network 200 V/400 rectified Hz). In order to obtain a coherent level of integration of the digital circuits, it was necessary to develop such modular supplies with a power density of about 1500 W/dm(sup 3) per unit of volume. In addition, so that these supplies can be established directly on a LRM simple face, their thickness had to be limited to 6.8 mm (case included/understood). To achieve this goal, a total integration that guaranteed the performances of the electric supplies, high frequency hybrid converters (of the order of MHz) were developed. After a presentation of the advantages of an architecture of distributed supply and a review of the main technical aims, this article describes the techniques and technologies implemented to achieve these goals. A thorough description of the developed modular supplies is given for delivered powers ranging between 50 W and 100 W and for various output voltages. Finally, the future developments planned to reach a power density of 4000 W/dm(sup 3) per unit of volume are reviewed. Transl. by CASI

Today's aircraft contain a multitude of different radio functions for communications, navigation and identification. The individual radio functions, like VHF/UHF, JTIDS/ MIDS, GPS or NIS, are each handled by an individual piece of equipment consisting of several LRU. In the absence of built-in redundancy, the failure of a single LRU can result in a failure of a radio function. In the future, individual radio functions need to be integrated in a modular system concept, the modular CNI system (communication - navigation - identification). Author

This report summarizes all work efforts completed under Contract F33615-87-C-0531, systems engineering design and technical analysis (SEDATA) for the Strategic Avionics Crew Station Design Evaluation Facility (SACDEF). This report consists of four main sections. Section 1 is an overview of SACDEF contract. Section 2 contains descriptions of specific tasks completed under the SEDATA for SACDEF contract. Section 3 contains conclusions and recommendations. Section 4 contains references, which includes reports and documentation produced under specific tasks of the contract. The Armstrong Laboratory has been involved in supporting the development and refinement of Strategic Bomber Crew Systems for almost 25 years. The SACDEF of the CFHI branch within the Human Engineering Division is responsible for research addressing crew station design and areas currently include aircrew workload evaluations, new control/display concepts, display device image quality, and electrophysiological correlates of crew performance. Specific emphasis is directed toward the development of advanced controls and displays for bomber aircraft, employing state-of-the-art, multifunctional display devices and computer programming techniques. An ongoing requirement has been to maintain the SACDEF B-52G Defensive Simulator and the B-1B Engineering Research Simulator (ERS) as designed, developed, tested, and delivered to Armstrong Laboratory under a previous contract. This report documents the work activities completed by Science Applications International Corporation for the SEDATA for SACDEF over the period 15 January 1988 through 14 May 1993. DTIC

RESPONSE OF THE B-1B AIR DATA SENSOR TO SIMULATED DUST CLOUD ENVIRONMENTS Technical Report, 17 Sep. 1992 - 15 Aug. 1993
Robert G. Oeding 1 Nov. 1994 106 p
(Contract DNA001-91-C-0021)
(AD-A286134; PDA-TR-1754-02-01; DNA-TR-93-164) Avail: CASI HC A06/MF A02

This report describes an experimental evaluation of the effects of dusty flow environments on the performance of the B-1B air data sensor (ADS). The evaluations were conducted in the DNA dust erosion facility which is located at PDA Engineering laboratories in Santa Ana, CA. The dust erosion facility was modified to provide a high speed dust jet with controlled moisture addition. Full-scale ADS probes were submerged in the dust flow and probe performance was monitored. Performance measurements included total, static, and angle-of-attack pressure outputs. Also pre- and post-test weights of the probes and pressure line dust filters were obtained in order to determine ingested particle mass. Both dry and wet flows included two levels of water addition to simulate cloud precipitation/moisture. The test configurations, procedures, and results are described. DTIC

EVALUATION OF THE HAWORTH-NEWMAN AVIONICS DISPLAY READABILITY SCALE M.S. Thesis
Charles F. Chiappetti Sep. 1994 63 p
(AD-A286127) Avail: CASI HC A04/MF A01

This study investigates the suitability of the Haworth-Newman Display Readability Rating Scale as a performance-based test and evaluation tool. This evaluation has been necessary to determine if the scale actually measures display readability, and if consistent, reproducible results are attainable. Background information on the scale's development is presented along with a brief description of display readability characteristics. A technique for systematic degradation of display readability and a method of displaying degraded symbology sets is introduced. A flight simulation experiment was conducted to obtain performance data, Haworth-Newman readability ratings, and participants' written comments for each of the degraded symbology set levels. Five Naval test pilots attempted to maintain specified heading, altitude, and airspeed while utilizing the ten levels of symbology sets and then used the Haworth-Newman scale to rate the display readability for each. Experimental results are discussed and recommendations presented. DTIC

TOUGHENED SILCOMP COMPOSITES FOR GAS TURBINE ENGINE APPLICATIONS Final Report, Apr. 1992 - Jun. 1994
G. S. Corman, K. L. Luthra, M. K. Brun, and P. J. Meschter Jul. 1994 115 p
(Contract DE-FC02-92CE-41000)
(DE95-002851; DOE/CE-41000/2) Avail: CASI HC A06/MF A02

The two main factors driving the development of new industrial gas turbine engine systems are fuel efficiency and reduced emissions. One method of providing improvements in both areas is to reduce the cooling air requirements of the hot gas path components. For this reason ceramic components are becoming increasingly attractive for gas turbine applications because of their greater refractoriness and oxidation resistance. Among the ceramics being considered, continuous fiber ceramic composites (CFCC's) are leading candidates because they combine the high temperature stability of ceramics with the toughness and damage tolerance of composites. The purpose of this program, which is part of DOE's CFCC initiative, is to evaluate the use of CFCC materials as gas turbine engine components, and to demonstrate the feasibility of producing such components from Toughened Silcomp composites. Toughened silcomp is a CFCC material made by a reactive melt infiltration process, and consists of continuous SiC reinforcing fibers, with an appropriate fiber coating, in a fully dense matrix of SiC and Si. Based on the material physical properties, the material/process improvements realized in Phase 1, and the preliminary design analyses from Task 1, they feel the feasibility of fabricating Toughened Silcomp with the requisite physical and mechanical properties for the intended applications has been demonstrated. Remaining work for Phase 2 is to further improve the system for enhanced oxidation resistance, incorporate additional process controls to enhance the reproducibility of the material, transition the fabrication process to the selected vendors for scale-up, develop a more complete material property data base, including long-term mechanical behavior, and fabricate and test preliminary 'representative part' specimens. Planar laser-induced fluorescence (PLIF) images of OH have been obtained from an optically accessible, lean burning high pressure combustor burning Jet-A fuel. These images were obtained using various laser excitation lines of the OH A (reverse arrow) X (1,0) band for several fuel injector configurations with pressures ranging from 1013 kPa (10 atm) to 1419 kPa (14 atm). Non-uniformities in the combusting flow, attributed to differences in fuel injector configuration, are revealed by these images. Contributions attributable to fluorescent aromatic hydrocarbons and complex fuel chemistries are also not evident. Author

TURBINE DESIGN AND APPLICATION
Arthur J. Glassman, ed. (National Aeronautics and Space Administration. Lewis Research Center, Cleveland, OH.) Cleveland, OH Jun. 1994 390 p
(NASA-SP-290; E-5666; NAS 1.21:290; LC-94-67487) Avail: CASI HC A17/MF A04

NASA has an interest in turbines related primarily to aeronautics and space applications. Airbreathing turbine engines provide jet and turboshaft propulsion, as well as auxiliary power for aircraft. Propellant-driven turbines provide rocket propulsion and auxiliary power for spacecraft. Closed-cycle turbine engines using inert gases, organic fluids, and metal fluids have been studied for providing long-duration electric power for spacecraft. Other applications of interest for turbine engines include land-vehicle (cars, trucks, buses, trains, etc.) propulsion power and ground-based electrical power. In view of the turbine-system interest and efforts at Lewis Research Center, a course entitled 'Turbine Design and Application' was presented during 1968-69 as part of the In-house Graduate Study Program. The course was somewhat revised and again presented in 1972-73. Various aspects of turbine technology were covered including thermodynamic and fluid-dynamic concepts, fundamental turbine concepts, velocity diagrams, losses, blade aerodynamic design, blade cooling, mechanical design, operation, and performance. The notes written and used for the course have been revised and edited for publication. Such a publication can serve as a foundation for an introductory turbine course, a means for self-study, or a reference for selected topics. Any consistent set of units will satisfy the equations presented. Two commonly used consistent sets of units and constant values are given after the symbol definitions. These are the SI units and the U.S. customary units. A single set of equations covers both sets of units by including all constants required for the U.S. customary units and defining as unity those not required for the SI units. Author

The report summarizes the research work into aircraft flight control concepts carried out by WL and DLR under the MoU. Addressed are the methods and scientific approaches used for two subtasks as Pilot vehicle integration and In-Flight Simulation Methodologies. Main emphasis from WL is laid on the different projects performed on the NT-33 and TIFS In-Flight Simulators in order to identify the influence of various system related parameters on longitudinal and lateral handling qualities. The work done by DLR describes the specific technique to be used for ground attack tasks (GRATE) for handling quality research and the development and system identification of DLR's new In Flight Simulator ATTAS. Based on the simulations performed in this phase 1 study, we show that Hopfield and RBF feedfoward network architectures may have a great potential in the control of nonlinear systems. In particular, Hopfield implementation of Lagrange multiplier method is suitable for real-time adaptive optimal control. Similarly, RBF feedforward neural network architectures are suitable for learning inverse dynamics and inverse trim in aircraft FCS applications. In addition, RBF feedfoward are easier to train than backpropagation sigmoid networks since RBF formulation results in linear parameters. The initial simulations we performed show very promising results as exemplified by the small control errors in closed-loop Simulations using the nonlinear /A-18 longitudinal dynamics. Further studies are needed to test the applicability of the techniques to real world problems and to study the robustness, stability and general reliability of the proposed neural techniques. Neural networks by themselves cannot be the panacea to all the nonlinear control problems. An effort has to be made to incorporate all the available knowledge about the dynamics system to achieve good performance. DTIC

Buffeting pressure measurements were made on the vertical tail surface of a full scale F/A-18 aircraft model in the National Full Scale Aerodynamics Complex at NASA Ames Research Center. Test variables included aircraft angle-of-attack, aircraft sideslip angle, and dynamic pressure. Accelerometers were used to obtain vertical tail accelerations. Pressure transducers were mounted on the starboard vertical tail. Steady and unsteady pressures were obtained. Unsteady pressure data were reduced to PSD and CSD forms. Both steady and unsteady RMS pressure coefficients are also presented. Volume 1 contains the general description of the model, the test program, and highlights of the reduced data. Volume 2 contains steady and unsteady RMS data. Volume 3 contains unsteady PSD results. Volume 4 contains unsteady CSD results. DTIC

USING THE BACKWARD TRANSFER PARADIGM TO VALIDATE THE AH-64 SIMULATOR TRAINING RESEARCH ADVANCED TESTBED FOR AVIATION Final Report, Jan. 1993 - Oct. 1993
John E. Stewart, II Sep. 1994 44 p
(AD-A285758; ARI-RR-1666) Avail: CASI HC A03/MF A01

The Simulator Training Research Advanced Testbed for Aviation (STRATA) is a modular simulation system for the AH-64 helicopter. The Adams and McAbee backward transfer of training paradigm was used to determine if AH-64 piloting skills transfer to STRATA. Ten AH-64 pilots participated in the experiment. They were asked to fly a mission scenario consisting of 13 single-pilot aircrew training manual (ATM) tasks. No orientation or practice sessions were given. Most participants rated STRATA as highly similar to the AH-64 in handling, but believed the visual display system had limitations for extremely low-altitude tasks like hovering. Performance ratings during the experiment by a senior instructor pilot (IP) indicated that of the total 130 task events, 88.5% were performed to ATM standards. After the experiment, four independent judges, all aviators, rank-ordered participant performance on the stationary hover task using output from STRATA's automated performance measurement system. Rankings showed agreement between judges and high correlation with IP ratings made during the experiment. DTIC

SUPER-HEAVY AIRCRAFT STUDY Final Report
Walter R. Barker and Carlos R. Gonzalez Apr. 1994 73 p
(AD-A279602; WES/TR/GL-94-12) Avail: CASI HC A04/MF A01

The test data for performance of flexible pavements were collected, sorted, and tabularized. The test data were analyzed using Boussinessq and layered elastic pavement models. To assist in the analysis, two computer programs were developed. The first program used the Boussinessq model to compute equivalent single-wheel loads. This program will compute the equivalent single-wheel load considering any selected cutoff distance. The second program used layered elastic theory for the analysis of pavements structures. The program has the capability of determining maximum pavement response for several response parameters, determining allowable loads for selected performance criteria, and computing a new layered elastic aircraft classification number. Several different performance criteria were developed including deflection criteria employing different cutoff distances, and strain criteria determined from the layered elastic pavement model. It was shown that deflection and strain criteria could be developed for the design of heavy multiwheel aircraft which would be independent of the number of tires in the aircraft gear. Performance criteria based on deflection, vertical strain, horizontal shear strain, maximum shear strain, and octahedral strain were incorporated into the layered elastic computer program to give predictions for pavement performance. Comparisons of the strain criteria were made with the current design criteria. DTIC

VAPOR GENERATOR WAND Patent Application
David B. Robelen, inventor (to NASA) 28 Nov. 1994 12 p
(NASA-Case-LAR-15058-1; NAS 1.71:LAR-15058-1; US-Patent-Appl-SN-359320) Avail: CASI HC A03/MF A01

In low speed wind tunnels it is often desirable to visualize airflow to augment observations made with instruments such as strain and pressure gages. Current technology devices for delivery of a vapor are bulky and thus disrupt local airflow. It is the object of this invention to provide a device capable of delivering a stream of vapor with a minimal effect on local airflow. The present invention achieves this object by utilizing a narrow tube as a heating device for producing the vapor. Running an electrical current through the tube provides resistive heating to a liquid which produces a vapor when boiled. As the entire heating and delivery portion of the device is simply a small cylinder the disruption to airflow within the tunnel is minimized. this allows an experimenter to place the source of vapor fairly close to a model without causing too much change to the model data. The novelty of the present invention lies in reducing the bulk of current technology devices by combining the acts of heating and delivery. Author

CHUNK PROJECTILE LAUNCH USING THE SANDIA HYPERVELOCITY LAUNCHER FACILITY
Lalit C. Chhabildas, Timothy G. Trucano, William D. Reinhart, and Clint A. Hall Jul. 1994 40 p
(Contract DE-AC04-94AL-85000)
(DE94-018494; SAND-94-1273) Avail: CASI HC A03/MF A01

An experimental technique is described to launch an intact 'chunk,' i.e. a 0.3 cm thick by 0.6 cm diameter cylindrical titanium alloy (Ti-6Al-4V) flyer, to 10.2 km/s. The ability to launch fragments having such an aspect ratio is important for hypervelocity impact phenomenology studies. The experimental techniques used to accomplish this launch were similar but not identical to techniques developed for the Sandia Hypervelocity Launcher

(HVL). A confined barrel impact is crucial in preventing the two-dimensional effects from dominating the loading response of the projectile chunk. The length to diameter ratio of the metallic chunk that is launched to 10.2 km/s is 0.5 and is an order of magnitude larger than those accomplished using the conventional hypervelocity launcher. The multidimensional, finite-difference (finite-volume), hydrodynamic code CTH was used to evaluate and assess the acceleration characteristics, i.e., the in-bore ballistics of the chunky projectile launch. A critical analysis of the CTH calculational results led to the final design and the experimental conditions that were used in this study. However, the predicted velocity of the projectile chunk based on CTH calculations was approximately 6% lower than the measured velocity of approximately 10.2 km/s. DOE

COLLECTED PAPERS OF THE SOAR/IFOR PROJECT, SPRING 1994 Technical Report

W. L. Johnson, Randolph M. Jones, David Keirsey, Frank V. Koss, and John E. Laird 25 Apr. 1994 105 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-92-K-2015)
(AD-A280063; CMU-CS-94-134; CSE-TR-207-94; ISI/SR-94-379) Avail: CASI HC A06

Since the summer of 1992, the Soar/IFOR research group has been building intelligent automated agents for tactical air simulation. The ultimate goal of this project is to develop automated pilots whose behavior in simulated engagements is indistinguishable from that of human pilots. This technical report is a collection of the research papers that have been generated from this project as of Spring 1994. The research covered in these papers spans a wide spectrum of issues in agent development such as explanation, managing situational awareness, managing multiple interacting goals, coordination between multiple agents, natural language processing, developing believable agents, event tracking, and the infrastructure to support agent development, including knowledge acquisition and use, interfacing to simulation environments, and developing low cost simulators. 16-FOOT TRANSONIC TUNNEL TEST SECTION FLOWFIELD SURVEY

J. A. Yetter and W. K. Abeyounis Dec. 1994 92 p
(RTOP 538-05-13-01)
(NASA-TM-109157; NAS 1.15:109157) Avail: CASI HC A05/MF A01

A flow survey has been made of the test section of the NASA Langley Research Center 16-Foot Transonic Tunnel at subsonic and supersonic speeds. The survey was performed using five five-hole pyramid-head probes mounted at 14 inch intervals on a survey rake. Probes were calibrated at freestream Mach numbers from 0.50 to 0.95 and from 1.18 to 1.23. Flowfield surveys were made at Mach numbers from 0.50 to 0.90 and at Mach 1.20. The surveys were made at tunnel stations 130.6, 133.6, and 136.0. By rotating the survey rake through 180 degrees, a cylindrical volume of the test section 4.7 feet in diameter and 5.4 feet long centered about the tunnel centerline was surveyed. Survey results showing the measured test section upflow and sideflow characteristics and local Mach number distributions are presented. The report documents the survey probe calibration techniques used, summarizes the procedural problems encountered during testing, and identifies the data discrepancies observed during the post-test data analysis. TESTING IN THE ARA TRANSONIC WIND TUNNEL

Dick Jordan Mar. 1994 48 p Original contains color illustrations
(ARA-Memo-395) Avail: CASI HC A03/MF A01

This note is an overview of the ARA 2.74 x 2.44m Transonic Wind Tunnel facility which covers the full Mach number range M = 0 to 1.4. A description of the main features of the tunnel circuit is given together with operational details. The test capabilities encompass a wide variety of model configurations which can be mounted on interchangeable full or half-span model carts. Load measurements are made using strain-gauge balances in conjunction with an appropriate sting or support strut. Several standard model support arrangements are provided but specialized rigs are frequently developed for particular requirements. High pressure air is available for tests involving propulsion simulation. An advanced data acquisition and data reduction system produces on-line corrected results which are presented on inter-active color graphic displays. Emphasis is placed on the consistently good flow quality in the working section, the high accuracy and repeatability of the aerodynamic measurements, the routine corrections incorporated in the data reduction, and the high productivity of testing in this tunnel. DEVELOPMENT OF QUIET-FLOW SUPERSONIC WIND TUNNELS FOR LAMINAR-TURBULENT TRANSITION RESEARCH Final Report, May 1990 - Dec. 1994

Steven P. Schneider Dec. 1994 55 p
(Grant NAG1-1133)
(NASA-CR-197286; NAS 1.26:197286) Avail: CASI HC A04/MF A01

This grant supported research into quiet-flow supersonic wind-tunnels, between May 1990 and December 1994. Quiet-flow nozzles operate with laminar nozzle-wall boundary layers, in order to provide low-disturbance flow for studies of laminar-turbulent transition under conditions comparable to flight. Major accomplishments include: (1) the design, fabrication, and performance-evaluation of a new kind of quiet tunnel, a quiet-flow Ludweig tube; (2) the integration of preexisting codes for nozzle design, 2D boundary-layer computation, and transition-estimation into a single user-friendly package for quiet-nozzle design; and (3) the design and preliminary evaluation of supersonic nozzles with square cross-section, as an alternative to conventional quiet-flow nozzles. After a brief summary of (1), a description of (2) is presented. Published work describing (3) is then summarized. The report concludes with a description of recent results for the Tollmien-Schlichting and Gortler instability in one of the square nozzles previously analyzed. Author

PORTABLE STATIC TEST FACILITY FOR SMALL, EXPENDABLE, TURBOJET ENGINES, PHASE 1 Final Report

Borislav Milatovic 28 Oct. 1994 127 p
(Contract DAAH01-94-C-R032)
(AD-A286337) Avail: CASI HC A07/MF A02

Test Devices, Inc. has completed the preliminary design for the Portable Static Test Facility (PSTF) for small, expendable, turbojet engines (50 - 1000 lb thrust) as part of the Phase 1 effort under SBIR contract DAAH01-94-C-RO32. The goal of providing a preliminary design for a development and test facility at a reasonable cost, assembled from standard, transportable modules and requiring minimum setup was achieved. During the Phase 1 activities a detailed analysis was performed that covered the description of engines to be tested, engine test procedures, general test specifications, test facility requirements and design considerations, installation, and engine control and test data requirements. From this a preliminary design for the portable test facility was prepared, plus a conceptual installation design and a preliminary design for the engine control and data system. DTIC

A CLEMENTINE COLLECTION: MOONGLOW
Jun. 1994 92 p
(AD-A286360; NRL/PU/1230-94-261) Avail: CASI HC A05/MF A01

The Clementine story began in 1990 when NASA administrator Richard Truly asked the Department of Defense to consider a joint NASA/DOD mission that would achieve goals mutually beneficial to both organizations. That request was given to the then Strategic Defense Initiative Organization (SDIO) to investigate. A mission was conceived to test the latest in space-based imaging components, using the moon and a near-earth asteroid as celestial targets. The Clementine mission is the result of those early investigations. This collection is an early sampling of the 1.8 million images acquired by the Clementine spacecraft. DTIC

SPACE FUNDAMENTALS FOR THE WAR FIGHTER Final Report
William G. Clapp 8 Feb. 1994 42 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A279703) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The quickening space technology revolution is as natural as life itself. Technology leads us to believe that anything is possible and that we are all privileged users. An understanding of some of the limitations of our space assets should moderate our expectations. The purpose of this paper is to provide a short and concise overview of the space environment and a fundamental understanding of space assets in order to understand their capabilities. The paper has been limited to the basic concepts of the atmosphere, rocket propulsion, launch vehicles, communications spectrum, and satellite assets. With the demise of the USSR threat, also gone are sufficient budgets that were going to provide the next generation of bigger and better satellites. We must accept the fact that next generation satellite security systems under development are now too expensive to field. Next generation satellite system funding may someday come again when a new threat diminishes our technological advantage. DTIC

SPACE TECHNOLOGY: FORCE MULTIPLIER OR FALSE SENSE OF SECURITY Final Report
Jessie W. Canaday 8 Feb. 1994 24 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A279726) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The Premise that space technology is a force multiplier is analyzed. Lessons learned from Desert Storm are discussed to show the advantages that space systems can bring to the battlefield and how unprepared the space community and our military forces were to execute a war using space technology. New space technology applications are described to show how space technology can enhance our military forces and the need for space control is discussed as more and more countries acquire space capabilities. Finally, by relying too much on technology and believing that technology will win all wars, we may garner a false sense of security. The paper concludes that space technology can be used as a force multiplier if we integrate space technology into all military operations and exercises, develop space doctrine to drive requirements for technology, educate our people on space systems, develop a coherent space control strategy, win the technology race and carefully assess our military requirements in the 'new world order'. RESTRICTED MASS TRANSPORT EFFECTS ON FREE RADICAL REACTIONS
A. C. Buchanan, III, P. F. Britt, and K. B. Thomas 1994 4 p Presented at the 208th American Chemical Society National Meeting, Washington, DC, 21-26 Aug. 1994
(Contract DE-AC05-84OR-21400)
(DE94-018136; CONF-940813-18) Avail: CASI HC A01/MF A01

Coal possesses a complex chemical and physical structure. The cross-linked, network structure can lead to alterations in normal thermally-induced, free-radical decay pathways as a consequence of restrictions on mass transport. Moreover, in coal liquefaction, access of an external hydrogen donor to a reactive radical site can be hindered by the substantial domains of microporosity present in coals. However, previous work indicates that diffusion effects do not appear to be playing an important role in this coal conversion chemistry. Several possible explanations for this phenomenon were advanced including the potential involvement of a hydrogen hopping/radical relay mechanism recently discovered model systems in the authors' laboratories. The authors have employed silica-anchored compounds to explore the effects of restricted mass transport on the pyrolysis mechanisms of coal model compounds. In studies of two-component systems, cases have been discovered where radical centers can be rapidly relocated in the diffusionally constrained environment as a consequence of rapid serial hydrogen atom transfers. This chemistry can have substantial effects on thermal decomposition rates and on product selectivities. In this study, the authors examine additional surfaces to systematically investigate the impact of molecular structure on the hydrogen atom transfer promoted radical relay mechanism. Silica-attached 1,3-diphenylpropane (approximately Ph(CH2)3Ph, or approximately DPP) was chosen as the thermally reactive component, since it can be considered prototypical of linkages in coal that do not contain weak bonds easily cleaved at coal liquefaction temperatures (ca. 4000 C), but which crack at reasonable rates if benzylic radicals can be generated by hydrogen abstraction. The rate of such hydrogen transfers under restricted diffusion will be highly dependent on the structure and proximity of neighboring molecules. DOE

The speed with which a promising military critical technology becomes available for military use is determined to a great extent by the effort and support focused on that technology. Determining which space technologies deserve this attention requires knowing at what performance level or technical parameter the technology becomes militarily critical. The Space System Technology Working Group (SSTWG) identified and parametrized those space technologies that are militarily critical, space unique, and dual-use and those that should be considered for cooperative agreements with industry and academia and memorandum of understanding (MOU) with other countries. This Executive Report provides government, industry, and academic personnel concerned with space technologies the purpose, methodology, and results of the SSTWG study. It includes tables that identify critical space technologies and their parameters. DTIC

This document provides information which shows that the NASA Lewis Research Center's Space Power Facility (SPF) will be ready to execute the Space Station electric power system thermal vacuum chamber testing. The SPF is located at LeRC West (formerly the Plum Brook Station), Sandusky, Ohio. The SPF is the largest space environmental chamber in the world, having an inside horizontal diameter of 100 ft. and an inside height at the top of the hemisphere of 122 ft. The vacuum system can achieve a pressure lower than 1 x 10(exp -5) Torr. The cryoshroud, cooled by gaseous nitrogen, can reach a temperature of -250 F, and is 80 ft. long x 40 ft. wide x 22 ft. high. There is access to the chamber through two 50 ft. x 50 ft. doors. Each door opens into an assembly area about 150 ft. long x 70 ft. wide x 80 ft. high. Other available facilities are offices, shop area, data acquisition system with 930 pairs of hard lines, 7 megawatts of power to chamber, 245K gal. liquid nitrogen storage, cooling tower, natural gas, service air, and cranes up to 25 tons. MILITARY STANDARD: TEST REQUIREMENTS FOR LAUNCH, UPPER-STAGE, AND SPACE VEHICLES

15 Sep. 1994 132 p Supersedes MIL-STD-1540B

(AD-A286627; MIL-STD-1540C; MIL-STD-1540B) Avail: CASI HC A07/MF A02

This Standard establishes the environmental and structural ground testing requirements for launch vehicles, upper-stage vehicles, space vehicles, and for their subsystems and units. In addition, a uniform set of definitions of related terms is established. The formal compliance tests for flight vehicle equipment start at the unit level of assembly and progress at each higher level of assembly until the entire launch system and the on-orbit system can be tested in their operational configurations. In addition, there may be development tests and evaluations at various levels of assembly, and in-process inspections and tests to avoid assembling a defective system. The formal compliance tests addressed in this document are qualification and acceptance at the unit, subsystem, and vehicle level as well as some of the integrated system prelaunch validation tests. COMPUTATIONAL DESIGN OF HYPERVELOCITY LAUNCHERS

T. Trucano and L. Chhabildas 1993 23 p Presented at the 1994 Hypervelocity Impact Symposium, Santa Fe, NM, 16-20 Oct. 1994

(Contract DE-AC04-94AL-85000)

(DE95-000744; SAND-93-3909C; CONF-9410131-7) Avail: CASI HC A03/MF A01

The Sandia Hypervelocity Launcher (HVL) uses impact techniques on a two-stage light-gas gun to launch flier plates to velocities in excess of 10 km/s. An important problem in designing successful third stage techniques for impact launching fliers to such velocities is detailed understanding of the interior ballistic performance of the third stage. This is crucial for preventing melt and fracture of the flier plates during the extraordinary accelerations that they undergo (accelerations on the order of 10(exp 9) g are typical on the HVL). We seek to optimize HVL launch conditions in order to achieve two major goals: first, to maximize the potential launch velocity for a given flier; and second, to allow different flier configurations. One tool that we can apply in studying HVL performance is the use of multi-dimensional wave propagation codes. We have used such codes, particularly the Sandia Eulerian code CTH, to study a variety of interior ballistics issues related to gun performance and launcher development for almost ten years. Recently this work has culminated in a major contribution to HVL design, namely the capability to launch 'chunk' fliers. The initial phases of design development were solely devoted to CTH computations that studied potential designs, identified problems, and posed possible solutions for launching chunk fliers on the HVL. Our computations sufficiently narrowed the design space to the point that systematic experimental progress was possible. Our first experiment resulted in the successful launch of an intact 0.33 gram titanium alloy chunk flier to a velocity of 10.2 km/s. The thickness to diameter ratio of this flier was approximately 0.5. DOE

LAUNCH VEHICLE FLIGHT CONTROL AUGMENTATION USING SMART MATERIALS AND ADVANCED COMPOSITES (CDDF PROJECT 93-05)

C. Barret Washington Feb. 1995 57 p

(NASA-TP-3535; M-770; NAS 1.60:3535) Avail: CASI HC A04/MF A01

The Marshall Space Flight Center has a rich heritage of launch vehicles that have used aerodynamic surfaces for flight stability such as the Saturn vehicles and flight control such as on the Redstone. Recently, due to aft center-of-gravity locations on launch vehicles currently being studied, the need has arisen for the vehicle control augmentation that is provided by these flight controls. Aerodynamic flight control can also reduce engine gimbaling requirements, provide actuator failure protection, enhance crew safety, and increase vehicle reliability, and payload capability. In the Saturn era, NASA went to the Moon with 300 sq ft of aerodynamic surfaces on the Saturn V. Since those days, the wealth of smart materials and advanced composites that have been developed allow for the design of very lightweight, strong, and innovative launch vehicle flight control surfaces. This paper presents an overview of the advanced composites and smart materials that are directly applicable to launch vehicle control surfaces. Author

DIGITAL FILTERING FOR DATA COMPRESSION IN TELEMETRY SYSTEMS
R. M. Bell 1994 6 p Presented at the ICSPAT 1994: Signal Procession Applications and Technology, Dallas, TX, 18-21 Oct. 1994
(Contract DE-AC04-94AL-85000)
(DE94-016611; SAND-94-8613C; CONF-9410164-3) Avail: CASI HC A02/MF A01

There are many obstacles to using data compression in a telemetry system. Non-linear quantization is often too lossy, and the data is too highly structured to make variable-length entropy codes practical. This paper describes a lossless telemetry data compression system that was built using digital FIR filters. The method of compression takes advantage of the fact that the optimal Nyquist sampling rate is rarely achievable due to two factors: (1) Sensor/transducers are not bandlimited to the frequencies of interest; and (2) Accurate, high-order analog filters are not available to perform effective band limiting and prevent aliasing. Real-time digital filtering can enhance the performance of a typical sampling system so that it approaches Nyquist sampling rates, effectively compressing the amount of data and reducing transmission bandwidth. The system that was built reduced the sampling rate of 14 high-frequency vibration channels by a factor of two, and reduced the bandwidth of the-data link from 1.8 Mbps to 1.28 Mbps. The entire circuit uses seven function-specific, digital-filter DSP's operating in parallel (two 128-tap FIR filters can be implemented on each Motorola DSP56200), one EPROM and a Programmable Logic Device as the controller. DOE

MATHEMATICAL MODELING OF A CLASS OF MULTIBODY FLEXIBLE SPACECRAFT STRUCTURES

Atul Kelkar, G. Dec. 1994 25 p
(RTOP 505-64-52-01)
(NASA-TM-109166; NAS 1.15:109166) Avail: CASI HC A03/MF A01

A mathematical model for a general multibody flexible spacecraft is obtained. The generic spacecraft considered consists of a flexible central body to which a number of flexible multibody structures are attached. The coordinate systems used in the derivation allow effective decoupling of the translational motion of the entire spacecraft from its rotational motion about its center of mass. The derivation assumes that the deformations in the bodies are only due to elastic motions. The dynamic model derived is a closed-form vector-matrix differential equation. The model developed can be used for analysis and simulation of many realistic spacecraft configurations. Author

The Helsinki University of Technology Satellite (HUTSAT) project started with the funding of the Academy of Finland and Helsinki University of Technology in January 1992. This is the first ever Finnish project concerning an orbiting satellite. The background, objectives and funding of the project are introduced. Then the subsystems of HUTSAT are described, each in its own chapter. Key design parameters are analyzed and then constraints to the other systems and payloads are discussed. The particle detector payload is presented. Product assurance (PA) aspects are discussed and HUTSAT PA principles are drawn. Finally, a short executive summary presents the key parameters of HUTSAT and its payload. NTIS

TWO-MICRON LASER ATMOSPHERIC WIND SOUNDER (LAWS) POINTING/TRACKING STUDY
Scott Manlief Jan. 1995 149 p
(Contract NAS1-19291; RTOP 233-01-01-03)
(NASA-CR-195012; NAS 1.26:195012) Avail: CASI HC A07/MF A02

The objective of the study was to identify and model major sources of short-term pointing jitter for a free-flying, full performance 2 micron LAWS system and evaluate the impact of the short-term jitter on wind-measurement performance. A fast steering mirror controls system was designed for the short-term jitter compensation. The performance analysis showed that the short-term jitter performance of the controls system over the 5.2 msec round-trip time for a realistic spacecraft environment was = 0.3 micro rad, rms, within the specified value of less than 0.5 micro rad, rms, derived in a 2 micron LAWS System Study. Disturbance modes were defined for: (1) the Bearing and Power Transfer Assembly (BAPTA) scan bearing, (2) the spacecraft reaction wheel torques, and (3) the solar array drive torques. The scan bearing disturbance was found to be the greatest contributing noise source to the jitter performance. Disturbances from the fast steering mirror reaction torques and a boom-mounted cross-link antenna clocking were also considered but were judged to be small compared to the three principal disturbance sources above and were not included in the final controls analysis. REENTRY VEHICLE ON-SITE INSPECTION TECHNOLOGY STUDY Technical Report, 6 Mar. 1992 - 19 May 1993
Mary C. Abe 1 Nov. 1994 116 p
(Contract DNA-MIPR-92-610)
(AD-A285960; DNA-TR-94-22) Avail: CASI HC A06/MF A02

A study group was tasked to develop possible reentry vehicle on-site inspection (RVOSI) scenarios and to recommend research into technologies that could address these scenarios. The task was accomplished by identifying RVOSI technology candidates and evaluating their advantages or disadvantages to compare to the visual protocol for RVOSI prescribed by the Strategic Arms Reduction Treaty (START) on the Reduction and Limitation of Strategic Offensive Arms. RVOIS technologies were evaluated with regard to inspection confidence, cost, intrusiveness, operational impact, and inspector burden. The RVOSI Technology Study identified no technology that readily solves the problems associated with START-prescribed visual inspection protocols. Recommendations for (1) further research in analytic modeling, (2) experimental studies to support this analytic work, and (3) data processing resulted from this study. Technology development for RVOIS appears to be primarily of interest if the technology provides enhanced confidence or additional inspection capability over visual inspections. DTIC

NONLINEAR DYNAMICS OF THE PLANAR PITCH ATTITUDE MOTION FOR A GRAVITY-GRADIENT SATELLITE Final Report, Jun. 1990 - Jun. 1994
Harry A. Karasopoulos Aug. 1994 220 p
(AD-A286407; WL-TR-94-3123) Avail: CASI HC A10/MF A03

The nonlinear dynamics of the planar pitch attitude motion for a gravity-gradient satellite in an elliptical orbit about a central body are investigated using phase diagrams, Poincare' maps, bifurcation plots, spectral density plots, Lyapunov exponents, and chaos diagrams. The satellite is assumed to be a rigid body influenced only by torques from an inverse-square gravitational field, and its major axis is assumed to be normal to the orbit plane. The resultant planar pitching motion is either periodic, quasiperiodic, or chaotic, depending upon the values of the system parameters, eccentricity and satellite inertia ratio. The relationships of the system parameters to the nonlinearity of the system are explored with chaos diagrams, which incorporate the results of the Lyapunov exponent calculations into a useful tool for predicting the onset of chaotic motion in parameter space. The border between regular and chaotic motion in the chaos diagrams is shown to be fractal. The dynamics of the basic problem supplemented by the addition of damping terms and an oblate, axially symmetric central body are also investigated. Strange attractors are found and the validity of Melnikov's method to predict the border between chaos and regular motion is examined. DTIC

The High Energy Transient Experiment (HETE), to be launched in 1995, will study Gamma-Ray Bursts in an unprecendented wide wavelength range from Gamma and X-ray to UV wavelengths. The X-ray range (2 to 25 keV) will be covered by 2 perpendicularly oriented 1-dimensional coded aperture cameras. These instruments cover a wide field of view of 2 sr and thus have a relatively large potential to locate GRB's to a fraction of a degree, which is an order of magnitude better than BATSE. The imaging design of these coded aperture cameras relates to the design of the coded apertures and the decoding algorithm. The aperture pattern is to a large extent determined by the high background in this wide field application and the low number of pattern elements ((approximately)100) in each direction. The result is a random pattern with an open fraction of 33%. The onboard decoding algorithm is dedicated to the localization of a single point source. DOE

INVESTIGATION OF ROCKET MOTORS 3 INCH NUMBER 1 Mk 4
L. M. Barrington May 1994 18 p
(AD-A284278; DSTO-TR-0017; DODA-AR-008-648) Avail: CASI HC A03/MF A01

In 1992, Aircraft Research and Development Unit (ARDU), RAAF, experienced two misfires with Rocket Motors, 3 in., No. 1, Mk 4, during a series of firings at Woomera. These motors were sampled from a batch manufactured in 1957, and subsequent to the misfires this batch was withdrawn from use. An alternate batch of motors manufactured in 1966 was available to ARDU. Tests were conducted on a number of these motors to advise on their suitability for use, and as a result, a further five years life was assigned with a recommendation to retest after that period. PROPULSION RESEARCH ON THE VARIABLE TANDEM MIRROR PLASMA ROCKET Final Report, 1 Feb. 1992 - 31 Jan. 1994
T. F. Yang and F. R. Chang-Diaz 7 Feb. 1994 90 p
(Contract NAS9-18372; AF-AFOSR-0345-89; AF Proj. 2308)
(NASA-CR-196310; NAS 1.26:196310; AD-A280009; PFC/RR-94-1; AFOSR-94-0319TR) Avail: CASI HC A05/MF A01

This report describes the progress made in the past two years as well as the overall picture of this research. In the past years, several-milestones have been achieved towards the realization of a practical space plasma thruster from the tandem mirror rocket experiment, i.e. the specific impulse, thrust, energy conversion efficiency, and mass flow-rate have been determined. The experiment operates at 9.4 kW of input power at an RF-to-plasma efficiency of 68%; The ion temperature is 172 eV (2,000,000 K) which gives an I(sub sp) of 12,852 s. The thrust is 76 mN (milli Newton) which is a high value for a low input power (9.4 kW) and very high I(sub sp), (12,852 s). The radiation loss was found to be very low. Most important, these results fall within our prediction. DTIC

SPACE-R THERMIONIC SPACE NUCLEAR POWER SYSTEM: DESIGN AND TECHNOLOGY DEMONSTRATION
1994 16 p
(Contract DE-AC03-92SF-19441)
(DE95-000713; DOE/SF-19441/T15) Avail: CASI HC A03/MF A01

The objective of this program is to design, develop, demonstrate, and advance the technology for thermionic space nuclear power system (TI-SNPS) to meet key functional requirements with reliable 5(approximately)40 kWe output and 18-month near-term/10-year long-term goals. A 40 kWe TI-SNPS point design will be prepared, and key technologies and critical components supporting that design will be validated. This program will produce an assessed design of a 40 kWe-EOL space nuclear power system. Phase 1 will provide for the performance of parametric trade studies and demonstration of key technologies, resulting in a preferred conceptual design for the TI-SNPS. The focus of the tasks is technology validation drive by the system design. DOE

RADIATION FROM ADVANCED SOLID ROCKET MOTOR PLUMES Final Report
Richard C. Farmer, Sheldon D. Smith, and Brian L. Myruski Dec. 1994 188 p Original contains color illustrations
(Contract NAS8-39370)
(NASA-CR-196554; NAS 1.26:196554; SECA-FR-94-18) Avail: CASI HC A09/MF A02; 4 functional color pages

The overall objective of this study was to develop an understanding of solid rocket motor (SRM) plumes in sufficient detail to accurately explain the majority of plume radiation test data. Improved flowfield and radiation analysis codes were developed to accurately and efficiently account for all the factors which effect radiation heating from rocket plumes. These codes were verified by comparing predicted plume behavior with measured NASA/MSFC ASRM test data. Upon conducting a thorough review of the current state-of-the-art of SRM plume flowfield and radiation prediction methodology and the pertinent data base, the following analyses were developed for future design use. The NOZZRAD code was developed for preliminary base heating design and Al2O3 particle optical property data evaluation using a generalized two-flux solution to the radiative transfer equation. The IDARAD code was developed for rapid evaluation of plume radiation effects using the spherical harmonics method of differential approximation to the radiative transfer equation. The FDNS CFD code with fully coupled Euler-Lagrange particle tracking was validated by comparison to predictions made with the industry standard RAMP code for SRM nozzle flowfield analysis. The FDNS code provides the ability to analyze not only rocket nozzle flow, but also axisymmetric and three-dimensional plume flowfields with state-of-the-art CFD methodology. Procedures for conducting meaningful thermo-vision camera studies were developed. Author

INTEGRAL ROCKET RAMJETS
R. F. Calzone Mar. 1994 49 p
(AD-A285135; PML-1994-B29; TDCK-93-2570) Avail: CASI HC A03/MF A01

A rough overview of the important aspects and problem areas associated with the development of Integral Rocket Ramjet (IRR) technology is given in this report. The IRR is a supersonic air-breathing concept in which the gas generator produces fuel-rich gases. These fuel-rich gases are burnt in the secondary combustion chamber with ambient air captured and decelerated in the inlet. During the boost phase, a solid propellant booster provides the thrust necessary to achieve the velocity at which the ramjet may be operated (about M = 2). The booster is integrated in the secondary combustion chamber. DTIC

NONLINEAR ACOUSTIC PROCESSES IN A SOLID ROCKET ENGINE Final Technical Report, 30 Sep. 1991 - 1 Jan. 1994
David R. Kassoy, Kadir Kirkkipn, and Qing Zhao 29 Mar. 1994 154 p
(Grant AF-AFOSR-0023-89)
(AD-A285606; AFOSR-94-0653TR) Avail: CASI HC A08/MF A02

A new formulation for chamber flow dynamics in a model of solid rocket engine shows that vorticity generation and convection are prominent physical features of the flow field. Analytical and fully computational methods are employed to describe a basically inviscid interaction between acoustic disturbances arising from specified boundary disturbances and a sidewall injected flow field which simulates propellant burning. The mathematical model, based on the Navier Stokes equations, is developed in terms of an initial value problem in order to describe the complete, natural chamber flow evolution arising from boundary driven disturbances. The approach is analogous to a direct numerical simulation, although contemporary perturbation methods are employed to extract specific spatial and temporal scales from the equations and boundary conditions. The results show that large unsteady vorticity is created at the injected surface (sidewall) and convects into the cylinder with the radial component of the injection flow velocity. DTIC

SSME HPOTP POST-TEST DIAGNOSTIC SYSTEM ENHANCEMENT PROJECT Final Report
Timothy W. Bickmore Cleveland, OH NASA Jan. 1995 169 p
(Contract NAS3-25883; RTOP 584-03-11)
(NASA-CR-4643; E-9372; NAS 1.26:4643) Avail: CASI HC A08/MF A02

An assessment of engine and component health is routinely made after each test or flight firing of a space shuttle main engine (SSME). Currently, this health assessment is done by teams of engineers who manually review sensor data, performance data, and engine and component operating histories. Based on review of information from these various sources, an evaluation is made as to the health of each component of the SSME and the preparedness of the engine for another test or flight. The objective of this project is to further develop a computer program which automates the analysis of test data from the SSME high-pressure oxidizer turbopump (HPOTP) in order to detect and diagnose anomalies. This program fits into a larger system, the SSME Post-Test Diagnostic System (PTDS), which will eventually be extended to assess the health and status of most SSME components on the basis of test data analysis. The HPOTP module is an expert system, which uses 'rules-of-thumb' obtained from interviews with experts from NASA Marshall Space Flight Center (MSFC) to detect and diagnose anomalies. Analyses of the raw test data are first performed using pattern recognition techniques which result in features such as spikes, shifts, peaks, and drifts being detected and written to a database. The HPOTP module then looks for combination of these features which are indicative of known anomalies, using the rules gathered from the turbomachinery experts. Results of this analysis are then displayed via a graphical user interface which provides ranked lists of anomalies and observations by engine component, along with supporting data plots for each. (NASA-CR-195320; E-8735; NAS 1.26:195320) Avail: CASI HC A05/MF A01

A comprehensive scenario of future missions was developed and applicability of different power technologies to these missions was assessed. Detailed technology development roadmaps for selected power technologies were generated. A simple methodology to evaluate economic benefits of current and future power system technologies by comparing Life Cycle Costs of potential missions was developed. The methodology was demonstrated by comparing Life Cycle Costs for different implementation strategies of DIPS/CBC technology to a selected set of missions. Author

MULTIPLE BURN FUEL-OPTIMAL ORBIT TRANSFERS: NUMERICAL TRAJECTORY COMPUTATION AND NEIGHBORING OPTIMAL FEEDBACK GUIDANCE Semiannual Status Report, 7 Jul. 1994 - 6 Jan. 1995
C.-H. Chuang, Troy D. Goodson, and Laura A. Ledsinger 5 Jan. 1995 37 p
(Grant NAG8-921)
(NASA-CR-197317; NAS 1.26:197317) Avail: CASI HC A03/MF A01

This report describes current work in the numerical computation of multiple burn, fuel-optimal orbit transfers and presents an analysis of the second variation for extremal multiple burn orbital transfers as well as a discussion of a guidance scheme which may be implemented for such transfers. The discussion of numerical computation focuses on the use of multivariate interpolation to aid the computation in the numerical optimization. The second variation analysis includes the development of the conditions for the examination of both fixed and free final time transfers. Evaluations for fixed final time are presented for extremal one, two, and three burn solutions of the first variation. The free final time problem is considered for an extremal two burn solution. In addition, corresponding changes of the second variation formulation over thrust arcs and coast arcs are included. The guidance scheme discussed is an implicit scheme which implements a neighboring optimal feedback guidance strategy to calculate both thrust direction and thrust on-off times. Author

ULTRAVIOLET EMISSION FROM ROCKET MOTOR PLUMES
David Kilpin Jun. 1994 23 p
(DSTO-TR-0002; AR-008-640) Copyright Avail: Issuing Activity (DSTO Aeronautical and Maritime Research Lab., GPO Box 4331, Melbourne, Victoria 3001, Australia)

Atmospheric limitations on the spectral region of the ultraviolet appropriate for detection of emissions from rocket motor plumes are considered. Origins of ultraviolet emission as spectral continua, bands and lines from the

rocket motor exhaust flow and its atmospheric interaction are discussed. The contrast of infrared emission arising mostly from major products and processes with ultraviolet emissions often resulting from trace constituents and minor pathways, indicates the more detailed knowledge of the rocket motor system required for modeling and prediction of ultraviolet signatures.

This paper presents an overview of the Nuclear Electric Propulsion Space Test Program (NEPSTP). The program goals, the proposed mission, the spacecraft, and the Topaz II space nuclear power system are described. The subject of flight qualification is examined and the inherent difficulties of qualifying a space reactor are described. The differences between US and Russian flight qualification procedures are explored. A plan is then described that was developed to determine an appropriate flight qualification program for the Topaz II reactor to support a possible NEPSTP launch. Refocusing of the activities of the Ballistic Missile Defense Organization (BMDO), combined with budgetary pressures, forced the cancellation of the NEPSTP at the end of the 1993 fiscal year. DOE

High friction and wear of turbine engine components occur during high temperature excursions above the oxidation threshold of the liquid lubricant. This paper reports on research to study the use of a high temperature self lubricating coating, PS 212 for back-up lubrication in the event of failure of the liquid lubricant. Pin on disk tests were performed under dry and boundary-lubricated conditions at disk temperatures up to 300 C. The liquid lubricant was a formulated polyol ester qualified under MIL L-23699. At test temperatures above the oil's thermal degradation level, the use of PS 212 reduced wear, providing a back-up lubricant effect. Author

SYNTHESIS AND STUDIES OF ORGANOMETALLIC PRECURSORS FOR CVD OF THIN FILM ELECTRONIC MATERIALS Final Report, Mar. 1991 - Aug. 1994
L. V. Interrante 30 Sep. 1994 12 p
(Contract N00014-91-J-1917)
(AD-A285834) Avail: CASI HC A03/MF A01

Cyclic molecular systems of the type, (A(XX')B(YY'))n (where A, B = Al, N or Si, C; X, X', Y, Y'= H, CH3, etc.; and n = 2 and 3), were studied as potential single-source precursors for the CVD of AlN and SiC films. These compounds provide the required elements for die product film already covalently bound to one another in a single, volatile molecular source and, in the case of the SiC precursors (where n = 2), they contain built-in ring-strain energy to lower the decomposition onset temperature. Efforts have included the study of the ((CH3)2AlNH2)3 yields AlN CVD system by mass spectrometric/time-of-flight (TOF) measurements and the investigation of substituted disilacyclobutanes as single-source SiC precursors. The mass spectrometric/TOF studies have indicated that a slow decomposition of the ((CH3)2AlNH2)3 (1) precursor to produce methane and a series of higher oligomeric products occurs during its vaporization at 75 to 100 C. These oligomeric species are believed to be intermediates formed in the gas-phase thermal decomposition of (1) to AlN. This precursor was used to deposit high quality AlN films up to 2 micrometers thick on Si and sapphire substrates in a LPCVD apparatus and is being tested for use in the deposition of AlN interface layers in Al2O3-reinforced metal matrix composites. Disilacyclobutane, (SiH2CH2)2, was found to yield stoichiometric, crack-free, adherent, polycrystalline SiC films on Si (100) and Si (111) surfaces by LPCVD at temperatures as low as 690 C. DTIC

NEW CHIRAL PYRIMIDINO-CROWN ETHER LIGANDS
J. Ty Redd, Jerald S. Bradshaw, Peter Huszthy, and Reed M. Izatt 11 May 1994 11 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-91-J-1710)
(AD-A279892; TR-28-ONR) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Two new chiral macrocyclic ligands containing the pyrimidine subcyclic unit have been prepared. Chiral dimethyl-substituted pyrimidino-crown 1 was prepared from 4-methoxy-5-methyl-2,6-pyrimidinedimethyl ditosylate 3 and chiral dimethyl-substituted tetraethylene glycol. Treatment of dimethyl 4-methoxy-5-methyl-2,6-pyrimidinedicarboxylate 4 with the diamine derivative of chiral dibenzyl-substituted tetraethylene glycol gave the chiral dibenzyl-substituted pyrimidino-crown diamide 2. Starting 4-methoxy-5-methyl-2,6-pyrimidinedimethanol 11 was prepared by a six step process from acetamidine hydrochloride and diethyl oxalpropionate. DTIC

THERMODYNAMIC AND NMR STUDIES OF SOLVENT EFFECT ON ENANTIOMERIC RECOGNITION FOR A CHIRAL ORGANIZ AMMONIUM CATION BY CHIRAL DIKETOPYRIDINO-18-CROWN-6 TYPE LIGANDS AT 25.0 C
Xian X. Zhang, Reed M. Izatt, Cheng Y. Zhu, and Jerald S. Bradshaw 11 May 1994 19 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-91-J-1710)
(AD-A279893; TR-30-ONR) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Three chiral diketopyridino-18-crown-6 type macrocycles have been shown to exhibit a high degree of enantiomeric recognition toward alpha-(1-naphthyl)ethylammonium perchlorate (NapEt) in various ratios of chloroform/methanol (CDCl3/CD3OD) and 1,2-dichloroethane/methanol (C2H4Cl2/CH3OH) solvent mixtures (from 100% to 10% methanol component). In most cases differences in log K values (delta(log) K) for (R)- and (S)-NapEt complexation with the chiral macrocycles are larger than 0.5. The degree of the enantiomeric recognition indicated by the delta(log) K value changes noticeably with the binary solvent components. The recognition is better in the solvents having a moderate methanol component than in the binary solvents having either a high a low methanol component. The highest degree of recognition is observed in 6/4 (v/v)

CDCl3/CD3OD and C2H4Cl2/CH3OH solvent mixtures and in a 7/3 (v/v) C2H4Cl2/CH3OH mixture for chiral (S,S)-1 macrocycle. Author (DTIC)

STRUCTURE OF DIBIS(DIETHYLDITHIOCARBAMATO) ZINC (2) Mu-BIS(DIETHYLPHOSPHINO)ETHANE TOLUENE(2) Technical Report No. 14
D. Zeng, M. J. Hampden-Smith, and E. M. Larson 6 May 1994 12 p
(Contract N00014-91-J-1258)
(AD-A279792) Avail: CASI HC A03/MF A01

Dibis(diethyldithiocarbamato) Zinc(2) mu-bis (Diethylphosphino)ethane (2)Toluene ((Et(sub 2) NCSS)2Zn)2 (mu-depe).2C7H8 Mr = 1114.4, monoclinic, P 2(sub l)/c, a = 12.960(1), b = 11.311(2), c = 20.129(5), beta = 96.46(1) deg, V = 2932 A(exp 3), Z = 2, D(sub x) = 1.254 g/cu cm, lambda (MoKa) = 0.070930 A, graphite monochromator, mu = 11.89/cm, F(000) = 1180, T = 298 K, final R = 0.055 (Rw = 0.072) for 2531 observed I greater than 3 sigma(I) reflections. The molecule is positioned symmetrically about an inversion center at the cell origin, which is situated in the center of the bridging diphosphine ligand. Toluene is disordered in this structure such that the rotation between the two positions of the methyl carbon is 36 deg. The geometry about the zinc can be described as distorted trigonal bipyramid. The Zn-P distance is 2.388 A and the zinc-sulphur distances range from 2.320 to 2.653 A. DTIC

CHEMICAL INTERACTIONS BETWEEN PROTEIN MOLECULES AND POLYMER MEMBRANE MATERIALS
J. A. Koehler and G. Belfort 25 Aug. 1994 4 p
(Contract DE-FG02-90ER-14114)
(DE95-001808; DOE/ER-14114/4) Avail: CASI HC A01/MF A01

During the past year, the authors have used the Surface Forces Apparatus (SFA) to measure the intermolecular forces between a model protein (hen egg-white lysozyme) and a model hydrophilic surface (mica), between lysozyme and itself and between lysozyme and a model hydrophobic surface composed of a crosslinked alkoxysilane surfactant (hexadecyltriethoxysilane, HTE). As expected, repulsive forces are dominant between the hydrophilic surfaces with the same charge (lysozyme-lysozyme) while attractive forces are dominant between oppositely charged surfaces (lysozyme-mica) and between the lysozyme and the hydrophobic surface. The DLVO theory for charged surfaces was found to agree with the results of the lysozyme-lysozyme interaction. Efforts also have been focused on trying to create a well-formed, defect-free monolayer of the HTE on the surface of the mica using a Langmuir-Blodgett (LB) apparatus. A smooth, defect-free surface is desired for the intermolecular force studies. Atomic force microscopy has been used to determine the topography of the HTE films. DOE

VIBRATIONAL OVERTONE SPECTROSCOPY OF PYRIDINE AND RELATED COMPOUNDS Technical Report, Sep. 1993 - Jun. 1994
Deanne Snavely and Joyce A. Overly 3 Jun. 1994 14 p
(Contract N00014-91-J-4130)
(AD-A280105; TR-14) Avail: CASI HC A03/MF A01

The vibrational overtone spectra of gaseous pyridine, 3-fluoropyridine, 2,6-difluoropyridine. and pyrazole have been recorded using photoacoustic absorption spectroscopy. The pyridine, 3-fluoropyridine, and 2,6-difluoropyridine overtone spectra exhibit two local mode progressions. These CH local modes are mixed and cannot be assigned to the separate CH oscillators at the 2,6 and 3,4 and 5 positions. The transition wavenumbers and peak widths are compared to those of benzene and pyrrole, both of which exhibit only one overtone peak at each quantum level. The fourth overtone spectrum of gaseous pyrazole displays two peaks. These spectra indicate that the presence of a lone pair perpendicular to the aromatic Pi system in aromatic heterocycles removes the local mode equivalency of the CH oscillators. DTIC

USE OF QUANTUM CHEMICALLY DERIVED DESCRIPTORS FOR QSAR MODELING OF REDUCTIVE DEHALOGENATION OF AROMATIC COMPOUNDS
E. Rorije, J. Richter, and W. J. G. M. Peijnenburg Apr. 1994 47 p
(PB95-132783; RIVM-719101015) Avail: Issuing Activity (National Technical Information Service (NTIS))

Encouraged by the strongly increasing calculative power of the present generation of personal computers, a strong tendency of using quantum-chemically derived descriptors is presently ground in the development of structure-activity relationships for various environmental end-points. In the study, quantum-chemically derived parameters are developed for a limited number of halogenated aromatic compounds to model the anaerobic reductive dehalogenation reaction rate constants of these compounds. It is shown that due to the heterogeneity of the set of compounds used, no single descriptor or combination of descriptors was able to adequately model the reaction under investigation. Thus subsets had to be created out of the group of compounds. NTIS

DEVELOPMENT AND DEMONSTRATION OF ADVANCED TECHNOLOGIES FOR DIRECT ELECTROCHEMICAL OXIDATION OF HYDROCARBONS (METHANOL, METHANE, PROPANE) Final Report
J. A. Kosek and A. B. LaConti Jul. 1994 8 p
(Contract DAAL03-92-C-0011)
(AD-A285094) Avail: CASI HC A02/MF A01

Direct methanol fuel cells use methanol directly as a fuel, rather than the reformate typically required by fuel cells, thus eliminating the reformer and fuel processing train. In this program, Giner, Inc. advanced development of two types of direct methanol fuel cells for military applications. Advancements in direct methanol proton-exchange membrane fuel cell (DMPEMFC) technology included development of a Pt-Ru anode catalyst and an associated electrode structure which provided some of the highest DMPEMFC performance reported to date. Scale-up from a laboratory-scale single cell to a 5-cell stack of practical area, providing over 100 W of power, was also demonstrated. Stable stack performance was achieved in over 300 hours of daily on/off cycling. Direct methanol aqueous carbonate fuel cells were also advanced with development of an anode catalyst and successful operation at decreased pressure. Improved materials for the cell separator/matrix and the hardware were also identified. Author (DTIC)

THE INFLUENCE OF PLY WAVINESS WITH NONLINEAR SHEAR ON THE STIFFNESS AND STRENGTH REDUCTION OF COMPOSITE LAMINATES Final Report, May 1992 - Apr. 1993
Travis A. Bogetti, John W. Gillespie, Jr. (Delaware Univ., Newark, DE.), and Mark A. Lamontia (Du Pont de Nemours, E. I. and Co., Newark, DE.) Oct. 1994 33 p
(Contract MDA972-89-C-0043; DA Proj. 1L1-62618-AH-80)
(AD-A285736; ARL-TR-585) Avail: CASI HC A03/MF A01

The influence of ply waviness with nonlinear shear material response on the mechanical performance of composite laminates is studied. An analytic model, based on a three-dimensional laminated media analysis, is developed to predict the effective nonlinear laminate behavior associated with ply waviness. An undulating 0 ply in a (90/0/90) sublaminate configuration and an undulating (+/- Beta) ply in a (90/ +/- Beta /90) sublaminate configuration are two types of ply waviness considered. An incremental loading strategy is employed wherein piecewise linear solutions are supposed to obtain the overall nonlinear stress/strain response of composite laminates with wavy plies. The analysis also predicts individual ply stress and strain distributions with the wavy ply configuration. The maximum stress failure criteria is used to predict ply failure in local regions with the wavy ply configuration, and a progressive failure methodology is adopted to permit local load redistribution. Results are presented which offer fundamental insight into the dominant mechanisms for stiffness and strength reduction in composite laminates exhibiting ply waviness and nonlinear shear material behavior. THE ENVIRONMENTAL DURABILITY OF FIBER REINFORCED CERAMIC MATRIX COMPOSITES Annual Report, 6 Jul. 1993 - 6 Jul. 1994
J. J. Brennan 15 Aug. 1994 62 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-93-C-0065)
(AD-A283750; UTRC-R94-970439-2) Avail: CASI HC A04

The main objective of this program is to investigate the environmental durability of ceramic matrix composites based on glass-ceramic and polymer pyrolysis matrices, with emphasis on the relationship between composite properties, microstructure, and chemistry, and the environment to which the composite is exposed. This environmental exposure will include the effect of oxidation, moisture, and corrosion, under conditions of high temperature and stresses. During the first year of the program, the composite system under study consisted of a barium-magnesium aluminosilicate (BMAS) glass-ceramic matrix reinforced with SiC/BN coated Nicalon SiC fibers. The results of these environmental durability tests on this composite system are discussed. DTIC

ANALYSIS OF THE PROGRESSIVE FAILURE OF BRITTLE MATRIX COMPOSITES Final Report
David J. Thomas Cleveland, OH NASA Feb. 1995 120 p
(Grant NAG3-862; RTOP 537-04-22)
(NASA-CR-195415; E-9337; NAS 1.26:195415) Avail: CASI HC A06/MF A02

This report investigates two of the most common modes of localized failures, namely, periodic fiber-bridged matrix cracks and transverse matrix cracks. A modification of Daniels' bundle theory is combined with Weibull's weakest link theory to model the statistical distribution of the periodic matrix cracking strength for an individual layer. Results of the model predictions are compared with experimental data from the open literature. Extensions to the model are made to account for possible imperfections within the layer (i.e., nonuniform fiber lengths, irregular crack spacing, and degraded in-situ fiber properties), and the results of these studies are presented. A generalized shear-lag analysis is derived which is capable of modeling the development of transverse matrix cracks in material systems having a general multilayer configuration and under states of full in-plane load. A method for computing the effective elastic properties for the damaged layer at the global level is detailed based upon the solution for the effects of the damage at the local level. This methodology is general in nature and is therefore also applicable to (0(sub m)/90(sub n))(sub s) systems. The characteristic stress-strain response for more general cases is shown to be qualitatively correct (experimental data is not available for a quantitative evaluation), and the damage evolution is recorded in terms of the matrix crack density as a function of the applied strain. Probabilistic effects are introduced to account for the statistical nature of the material strengths, thus allowing cumulative distribution curves for the probability of failure to be generated for each of the example laminates. Additionally, Oh and Finney's classic work on fracture location in brittle materials is extended and combined with the shear-lag analysis. The result is an analytical form for predicting the probability density function for the location of the next transverse crack occurrence within a crack bounded region. The results of this study verified qualitatively the validity of assuming a uniform crack spacing (as was done in the shear-lag model). Author

COMPARISON OF THE DYNAMIC FATIGUE BEHAVIOR OF TWO MONOLITHIC SiC AND AN Al2O3/SiC COMPOSITE
K. Breder and V. J. Tennery 1994 11 p Presented at the 18th Annual Conference on Composites and Advanced Ceramics, Cocoa Beach, FL, 9-14 Jan. 1994
(Contract DE-AC05-84OR-21400)
(DE94-017751; CONF-940135-8) Avail: CASI HC A03/MF A01

Two monolithic silicon carbides, NT230 siliconized SiC from Norton Saint Gobain and sintered (beta)-SiC from Coors, and a silicon carbide particulate reinforced alumina ceramic composite from Lanxide, which all are candidate materials for pressurized heat exchangers in coal-fired power plants have been evaluated. The fast fracture flexure strength was measured as a function of temperature. All candidate materials retained a sufficient strength level up to 1400 C. The susceptibility to slow crack growth (SCG) was evaluated by the dynamic fatigue method at 1100 C and 1400 C. None of the materials exhibited SCG at 1100 C. At 1400 C the siliconized SiC ceramic showed limited SCG and the composite ceramic exhibited creep damage when stressed to 50% of fast fracture strength at the intermediate and slow stressing rates. This prevented the evaluation of the SCG properties of this material at 1400 C. Fractography supported the mechanical observations and with the exception of the specimens which exhibited creep damage, only the siliconized SiC showed a small SCG damage zone at long times at 1400 C. THE THERMAL CONDUCTIVITY OF CARBON COATED SILICON CARBIDE FIBERS EMBEDDED IN A SILICON CARBIDE MATRIX
S. C. Beecher, R. B. Dinwiddie, and R. A. Lowden 1993 12 p Presented at the 22nd International Thermal Conductivity Conference, Tempe, AZ, 7-10 Nov. 1993
(Contract DE-AC05-84OR-21400)
(DE94-017758; CONF-9311131-4) Avail: CASI HC A03/MF A01

The room temperature thermal conductivity has been measured for a series of composite materials composed of carbon coated silicon carbide (SiC) fibers embedded in a SiC matrix. The composite samples consisted of 0/30(degree) bi-directional plain weave Nicalon fibers coated with varying thicknesses of pyrolitic carbon and infiltrated with SiC by the forced flow chemical vapor infiltration process to form the matrix. The fiber volume fraction was held constant at 0.423 +/- 0.012 and from 0.03 (mu)m - 0.983 (mu)m, with the fibers of one sample left uncoated. Results transverse to fiber direction show significant differences with the introduction and subsequent increase in the carbon coating thickness. The thermal conductivity decreased for all the coated samples compared to the uncoated sample coating thickness compared to the sample with the thinnest carbon coating. DOE

Routbort Jun. 1994 14 p Presented at the 96th Annual Meeting of the American Ceramic Society, Indianapolis, IN, 24-28 Apr. 1994
(Contract W-31-109-eng-38)
(DE94-018387; ANL/ET/CP-83963; CONF-940416-25) Avail: CASI HC A03/MF A01

The elastic anisotropy in hot-pressed samples of (beta)-Si3N4 monolithic polycrystalline composites and in composite with 5 to 35% (beta)-Si3N4 whiskers have been investigated at room temperature by high precision acoustic interferometry. All of the samples, including the monolithic Si3N4, show anisotropy characterized as transverse isotropic about the hot-pressing (HP) direction and are described using the five elastic stiffness moduli for hexagonal symmetry. The principal anisotropy is revealed in the shear modulus difference, C(66) - C(44) /C(sub 44), which increases from 7% in the monolithic sample to 15% in samples with 10% or more whiskers. All the stiffness moduli except for C(44) increase with the addition of whiskers. Young's modulus in the HP direction is 5% smaller than in the HP plane in all samples. The whiskers enhance the shear anisotropy produced by the in situ elongated (beta)-grains. DOE

LOW TEMPERATURE SYNTHESIS OF SEMICONDUCTOR MATERIALS Annual Report, 15 Aug. 1993 - 14 Aug. 1994
Philip Boudjouk 14 Sep. 1994 14 p
(Contract F49620-92-J-0431)
(AD-A285120; AFOSR-94-0600TR) Avail: CASI HC A03/MF A01

This report summarizes the results obtained in the second year of the grant. During this time experiments were conducted which demonstrated that phenyl groups on heavier main group atoms undergo migration with great facility. This mobility has been utilized to prepare novel materials with a broad range of semiconducting and optoelectronic properties. Gallium arsenide and gallium phosphide have been prepared at modest temperatures (approx. 400 C) from easily prepared single source precursors. Work conducted in this time period led to the discovery that ternary compounds composed of tin, sulfur and selenium can be prepared in high yields at approx. 400 C as phase pure materials in nonstoichiometric ratios from readily available compounds. Conventional procedures call for temperatures greater than 1000 C. Also discovered was that pyrolysis of perbenzylated compounds has advantages over the alkylated analogues among which are lower toxicity, faster decomposition times and lower contamination of target products. NOVEL ELECTROCHEMICAL MATERIALS PREPARED BY SOL-GEL CHEMISTRY Annual Report
Gregory C. Farrington, John O. Thomas, and Stig Friberg 15 Jul. 1994 12 p Prepared in cooperation with Uppsala Univ., Sweden and Clarkson Univ., Potsdam, NY Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-90-J-1156)
(AD-A286310) Avail: CASI HC A03

This program is directed at preparing and characterizing novel gels, xerogels, and aerogels which, because of their conductivity and/or charge storage capability, have unusual electrochemical characteristics. Typical materials of interest are the transition-metal oxides currently being exploited in their polycrystalline forms in the electrodes of the lithium batteries. Characterization involves structural and electrochemical studies, atomic force microscopy, and novel x-ray diffraction and mu-FTIR techniques. One of several novel contributions of this work is the use of molecular dynamics simulation as a powerful source of insight into surface and bulk mechanisms in sol-gel synthesized materials. DTIC

INTERNATIONAL COLLABORATION PROGRAM ON INNOVATIVE CHEMICAL PROCESSING OF SUPERIOR ELECTRONIC AND OPTICAL MATERIALS Final Report, 15 Jul. 1991 - 14 May 1994
John D. Mackenzie Jul. 1994 21 p
(Grant AF-AFOSR-0317-91)
(AD-A285122; AFOSR-94-0617TR) Avail: CASI HC A03/MF A01

An international collaborative research project to investigate the preparation and properties of quantum dot materials based on CdS microcrystals in various matrices has been carried out from July 1991 to May 1994. The team consisted of Professor J.D. Mackenzie (P.I.), Professor M. Yamane of the Tokyo Institute of Technology, and Professor N. Peyghambarian of the University of Arizona. Samples were prepared by the Sol-Gel method with sodium borosilicate glass and ormosils (organically modified silicates) as the matrices. The samples showed no photodarkening effect and have chi cubed values up to 10(exp -6) cgs units. Techniques were developed to limit the size distribution of the Cds while maintaining high concentrations (greater than 10%). Waveguides were fabricated by the ion-exchange method. At their present developmental stages, the samples suggested the possibility that they can be made into a new type of laser and also offer the potentials of achieving photochemical hole-burning at room temperature. THE THERMAL CONDUCTIVITY OF CARBON-FIBER REINFORCED METAL MATRIX COMPOSITES
R. B Dinwiddie, S. C. Beecher, P. V. Arya (Materials and Electrochemical Research Corp., Tucson, AZ.), and J. C. Withers (Materials and Electrochemical Research Corp., Tucson, AZ.) 1993 13 p Presented at the 22nd International Thermal Conductivity Conference, Tempe, AZ, 7-10 Nov. 1993
(Contract DE-AC05-84OR-21400)
(DE94-017767; CONF-9311131-3) Avail: CASI HC A03/MF A01

High thermal conductivity metal matrix composites are being considered for heat sink applications in fusion energy, automotive and aerospace industries. The addition of P-120 carbon fibers was found to enhance the thermal conductivity of both aluminum and copper matrix composites. However, above 60 volume percent loading, the thermal conductivity of the composites tends to decrease. The titanium used as a fiber interface was found to be deleterious to the thermal conductivity of the copper matrix. Small diameter diamond particle additions tend to reduce the thermal conductivity of both the copper and aluminum matrix composites. This is explained in terms of the dominance of thermal boundary resistance due to the large surface to volume ratio of the small diamond particles. DOE

A technique has been developed to fracture irradiated Nicalon SiC fibers in a Scanning Auger Microprobe (SAM) and analyze the fracture surfaces without contaminating the specimen chamber. The technique, which was evaluated using as-received fibers, requires only minor modification of two standard specimen holders and should be applicable to other fibers or materials that can be broken under low loads in bending. The technique is simple, rapid, reduces beam charging, and eliminates the need for ion sputtering. DOE

(Contract N00014-91-J-4008)
(AD-A279661) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The goal of this program is to investigate new dielectrics, metals and processes for the fabrication and characterization of multi-chip modules (MCM) which hold the promise of excellent performance, cost and yield for high frequency MCM's. First, the processes for using noble metals (gold and silver) as the interconnection metallization in the module have been investigated. The noble metal process can have fewer processing steps (particularly for gold) than the equivalent copper process and are potentially lower cost, particularly when high reliability is important. A silver process has been developed so that the silver maintains its bulk conductivity (highest of conventional metals) and has low residual stress during high temperature processing. Commercialization of the silver process is being considered. Second, a unique adhesion material has been investigated and is currently being tested for commercial use. We are in the process of evaluating the process with n-Chip and transferring the technology to them. DTIC

(Contract N00014-91-J-1269)
(AD-A279693) Avail: CASI HC A01/MF A01

This is the final report on a project funded for 3 years by ONR. The project was very successful; it resulted in the discovery of many new solid state ternary nitrides. Since there were so few ternary nitrides known, and since many of the binary nitrides, such as TiN, AlN and Si3N4 are so technologically useful, our aim was to explore the synthesis, structural chemistry and properties of ternary nitrides. Prior to our work very few ternary nitrides, other than those formed by alloying binaries and having simple binary like structures, were known. We have shown that there is indeed a very large class of such ternary nitrides. DTIC

ATTACHMENT METHODOLOGY FOR COMPOSITE CYLINDER ASSEMBLY Patent
Roger M. Crane, inventor (to Navy) and Paul Coffin, inventor (to Navy) 27 Sep. 1994 10 p Filed 30 Sep. 1993
(AD-D016578; US-Patent-5,349,738; US-Patent-Appl-SN-128786; US-Patent-Class-29-434) Avail: US Patent and Trademark Office

Cylinder-to-cylinder attachment method and construction featuring nonutilization of mechanical fasteners or bonding, especially advantageous for attachment of cylinders which are composite or to be subjected to hydrostatic pressure. A fastening ring is interpositionally and rotatively engaged and aligned with a toothed axial end of each cylinder whereby the inwardly radial teeth for each cylinder appropriately mesh with the outer grooved circumferential surface of the fastening ring. The resultant joint is easily detachable and less susceptible than conventional joints to damage, breakage, degradation, stress concentrations and fluid infiltration. DTIC

The program goals for the first quarter were to locate and contact potential manufacturers of these components, evaluate their level of interest, and begin discussions of the type and design of the prototypes to be fabricated for their evaluation. Thoughtful discussion at this stage would result in fabricating prototypes which answer the greatest number of questions possible for a given manufacturer at the lowest cost to this program. In the present economy many manufacturing firms have almost no funds for testing and evaluating new materials. This places a greater burden on the data obtained from outside laboratories. In many cases this data will be used to make that first evaluation on MRCC's (metal reinforced carbon composites) suitability for a given application and give firms the confidence to commit to a evaluation program. In Exhibit 1, which is attached to this report the authors have the first set of data from outside laboratories. This has been incorporated into a paper which has been accepted for the annual STLE (Society of Tribologist and Lubrication Engineers) conference in Chicago in the spring of 1995. The authors are in active contact with over 20 companies. Some of these have advanced to the point of requesting prototypes and the drawings have been submitted. In addition two groupings of companies have been formed to pool their resources in combined evaluation programs. These are described. The authors are in the process of manufacturing the first prototypes. DOE

DETECTION OF ENVIRONMENTAL DETERIORATION IN FIBER REINFORCED COMPOSITES BY FT-RAMAN SPECTROSCOPY, PHASE 1 Final Report, 30 Jul. 1993 - 30 Apr. 1994
Stuart Farquharson, Anthony Bananno, Rosemary Basilakis, Martin Carangelo, and Marie DiTaranto May 1994 47 p
(Contract DAAL01-93-C-4058)
(AD-A279763) Avail: CASI HC A03/MF A01

A number of advanced fiber reinforced organic matrix composites are being developed and applied in the aerospace industry. In these applications, the composites may be exposed to a variety of harsh environments, which may induce chemical and physical changes in the composite material, and ultimately lead to component failure. The successful use of these composites, therefore, requires methods to reliably detect and assess these changes. During this Phase 1 Program, a fiber optic based Fourier transform Raman spectrometer was specifically developed to perform nondestructive evaluation of environmentally damaged composites. Specifically, graphite and Kevlar reinforced epoxy and polyimide composite samples were subjected to thermal cycling, moisture exposure and ultraviolet irradiation. Three point flexure tests were used to measure flexural strength, flexural modulus, failure strain and failure load to assess induced mechanical property changes in the composites. Reflectance infrared spectra of the sample surfaces, as well as transmission infrared spectra of evolved gas phase chemical species were used to further characterize these changes. DTIC

(AD-A286081; ARL-TN-35) Avail: CASI HC A03

Helmholtz coils are used to develop uniform magnetic fields for a variety of research applications. Helmholtz coils can be easily constructed, and the fields easily calculated. This makes them especially useful in calibrating sensors and numerous other low frequency magnetic field testing applications. This particular report will discuss the calculation and measurement of Helmholtz coil fields to be used for testing of composite materials to low frequency magnetic fields. DTIC

TOPOGRAPHY OF NEUTRON SCATTERING FROM DIBLOCK COPOLYMER FILM

Z. Cai and T. P. Russell (International Business Machines Corp., San Jose, CA.) 1994 21 p
(Contract W-31-109-eng-38)
(DE95-001457; ANL/IPNS/PP-79589) Avail: CASI HC A03/MF A01

The surface structure of a multilayered film of symmetric perdeuterated diblock copolymers of polystyrene and polymethylmethacrylate, denoted P(d-S-b-d-MMA), was investigated by neutron scattering at grazing incidence. The film surfaces were covered by islands or holes of uniform height with a lateral size of several micrometers. With the angle of incidence fixed, the off-specular neutron scattering was measured as function of scattering angle and neutron wavelength. The off-specular scattering intensity shows ridges at constant q(sub z), the momentum transfer along the surface normal. The scattering arises from the surface domains. It was found that the off-specular ridges developed from minima in the oscillations in the specular profile corresponding to domain height. The characteristic of the off-specular scattering, which is different from that of the off-specular scattering due to the conformal roughness in a multilayered film, is interpreted in terms of the correlations of the surface domains. ROLE OF INTERNAL STRESSES IN FRACTURE BEHAVIOR OF ENGINEERING COMPOSITES

J. P. Singh, D. Singh, D. S. Kupperman, and S. Majumdar May 1994 15 p Presented at The Metallurgical Society (TMS) Conference on High Performance Composites, Rosemont, IL, 10-15 Oct. 1994
(Contract W-31-109-eng-38)
(DE95-001106; ANL/ET/CP-82224; CONF-9410184-3) Avail: CASI HC A03/MF A01

Microstructure and fracture behavior of SiC(f)/Si3N4 matrix composites, and of Ag-particulate/YBa2Cu3O(x)(YBCO) superconductor matrix composites, together with internal residual strains in composite constituents, have been evaluated as a function of reinforcing-fiber, particulate content, and processing variables. Residual strains were measured by neutron diffraction with the Intense Pulsed Neutron Source and Powder Diffractometer at Argonne National Laboratory. Internal radial strains on SiC fibers in SiC(f)/Si3N4 composites decreased from 0.0015 at 8.4 vol.% fibers to 0.0010 at 23.3 vol.% fibers. This decrease in radial strain with increasing fiber volume fraction is expected to reduce frictional and hence interfacial sliding stresses between SiC fibers and Si3N4 matrix; this is in agreement with interfacial shear strengths measured by the fiber pushout technique. Similar relationships between residual strain and interfacial shear strength was observed for composites hot isostatically pressed (HIPed). For YBCO-AG composites, tensile strain in the Ag phase was as high as 0.085%, whereas compressive strain in the YBCO phase reached 0.09%. The presence of compressive strain (stress) improved the strength of YBCO from 200 to 223 MPa. Implications of the effects of residual stresses on interfacial characteristics and resulting composite mechanical properties and fracture behavior will be discussed. DOE

The present invention provides a fixture for supporting an elongated specimen for crush testing. The fixture comprises a base plate, four guiding rods, a sliding plate, four support rods and two collars. The guiding rods connect to the base plate and extend in a direction substantially perpendicular to the base plate. The sliding plate has linear bearings which encircle the guiding rods and enable translation of the sliding plate along the axis of each guiding rod. The four supporting rods mount to the base plate and also extend in a direction substantially perpendicular to the base plate. Each support rod has a keyway for a wedge which contacts the elongated specimen and holds the specimen in place during crushing. Each collar lies above the sliding plate and holds a pair of support rods on their ends opposite the ends connected to the base plate. A spherical bearing sits on top of the sliding plate and transfers an applied load to the sliding plate, which moves downward and crushes the elongated specimen. Author

IMPLEMENTATION OF THE MILITARY HANDBOOK 17 FOR POLYMER MATRIX COMPOSITES AND METAL MATRIX COMPOSITES Progress Report, 1-30 Sep. 1994

Crystal H. Newton Oct. 1994 15 p Revised
(Contract DAAL01-93-C-4064)
(AD-A285629; MSC-TPR-3458/CA07-Rev) Avail: CASI HC A03/MF A01

Project effort this month concentrated on support of the Coordination Group meeting and data analysis. Information for the meeting booklet was submitted to ARL. Agendas for two working groups were revised based on progress on data analysis and discussions during the briefing meeting in August. These revisions were sent to the chairmen of working groups involved. The log of comments submitted for MIL-HDBK-17 was updated and distributed to the working group of chairmen. The executive session, the meeting of the MIL-HDBK-17 working group chairmen, was held on the afternoon of 19 September 1994. DTIC

Based on the requirements of Contract Modification 0003, preparation of input of handbook from the 27th (Portland), 28th (Alexandria), and 29th (Monterey) meetings has been planned. All figures in the revisions and new sections will be scanned and included as part of the WordPerfect files. Corrections to Volume 1, Chapter 7 have been received from the Structural Joints working group. These corrections will be implemented in the next change notice or revision. The following draft sections from the 29th meeting in Monterey have been approved: Volume 1: Toxicity, Health

Hazards, and Safety; Definitions - new and revised definitions; General (Lamina, Laminate, and Fabric Mechanical Property Tests) - revision; Organization of data in handbook - revision. Volume 3: Polyimides - new; Amorphous Thermoplastics - new material to be appended; Laminate Strength and Failure - revision; Compression postbuckling and crippling - replaces Section 4.7.1.8. DTIC

TIME-DEPENDENT DEFORMATION OF TITANIUM METAL MATRIX COMPOSITES Final Report
C. A. Bigelow (Federal Aviation Administration, Atlantic City, NJ.), Y. A. Bahei-El-Din (Cairo Univ., Egypt.), and M. Mirdamadi Jan. 1995 32 p
(Contract NAS1-19708; RTOP 505-63-50-04)
(NASA-CR-195030; NAS 1.26:195030) Avail: CASI HC A03/MF A01

A three-dimensional finite element program called VISCOPAC was developed and used to conduct a micromechanics analysis of titanium metal matrix composites. The VISCOPAC program uses a modified Eisenberg-Yen thermo-viscoplastic constitutive model to predict matrix behavior under thermomechanical fatigue loading. The analysis incorporated temperature-dependent elastic properties in the fiber and temperature-dependent viscoplastic properties in the matrix. The material model was described and the necessary material constants were determined experimentally. Fiber-matrix interfacial behavior was analyzed using a discrete fiber-matrix model. The thermal residual stresses due to the fabrication cycle were predicted with a failed interface, The failed interface resulted in lower thermal residual stresses in the matrix and fiber. Stresses due to a uniform transverse load were calculated at two temperatures, room temperature and an elevated temperature of 650 C. At both temperatures, a large stress concentration was calculated when the interface had failed. The results indicate the importance of accuracy accounting for fiber-matrix interface failure and the need for a micromechanics-based analytical technique to understand and predict the behavior of titanium metal matrix composites. DAMAGE TOLERANCE OF CARBON FIBRE POLYETHERETHERKETONE LAMINATES [KOLFIBER/POLYETERETERKETON-LAMINATS SKADETALIGHET]
F. Larsson Mar. 1994 20 p In SWAHILI
(PB95-131611; FOA-A-20056-2.4) Avail: Issuing Activity (National Technical Information Service (NTIS))

An investigation has been made of the ballistic damage tolerance of carbon fiber polyetheretherketone laminates (AS4/PEEK,APC-2) with near quasi-isotropic lay-up. The results indicate that a 40% greater compressive stress can be applied to the material compared to a carbon fiber epoxy composite of the first generation (T300/914) without causing collapse when impacted with penetrating steel balls with a diameter of 6,00 mm. Compared with a composite with a toughened epoxy matrix (HTA7/6376) the composite studied has a 20% greater capacity. The ranking order of the composites with respect to ballistic damage tolerance is there-with the same as for low velocity impact damage tolerance. This conclusion is not self evident since there are differences in morphology and composition between the three matrices. Therefore it has been important to find out if an increased impact velocity changes the ranking order of the composites. The ranking order is however unchanged. The delamination energies of the three mentioned composites at high crack propagation velocity have been determined for unidirectional specimens by means of a pendulum impactor. The energy required to delaminate the APC-2 specimens is of the order of three times that of the other composites. NTIS

DEPOSITION AND PROPERTIES OF NOVEL NITRIDE SUPERLATTICE COATINGS Progress Report, 28 Sep. 1990 - Oct. 1994
S. A. Barnett, W. D. Sproul, and M. S. Wong Oct. 1994 3 p
(Contract DE-FG02-90ER-45434)
(DE95-002945; DOE/ER-45434/4) Avail: CASI HC A01/MF A01

The major effort during this report period was to elucidate the hardening mechanisms in polycrystalline superlattices. Since the last progress report, the authors have been working on theoretical modeling of hardening mechanisms in superlattices and have carried out detailed studies of two new polycrystalline superlattice coatings, NbN/VN and CrN/TiN, which were produced using an opposed, dual-cathode, high-rate, reactive, unbalanced-magnetron sputtering system. Significant hardness enhancement the above rule-of-mixture hardness value was found for the CrN/TiN, but not for the NbN/VN. Correlating these results with prior results for TiN/NbN and TiN/VN shows that the major hardening mechanism in polycrystalline superlattices is the difference in layer elastic moduli, which is minimal in the NbN/VN case. The modulus difference provides a barrier to dislocation flow across the layers. In the absence of modulus-difference hardening in NbN/VN, it was found that other hardening mechanisms such as coherency strains and the small grain sizes observed in the superlattices play a minor role. The results achieved in this report period are described in this paper along with publications and presentations. DOE

PROCESSING AND MECHANICAL PROPERTIES OF LAMINAR Al2O3-Ni3Al COMPOSITES
J. H. Schneibel and K. B. Alexander 1994 7 p Presented at the Spring Meeting of the Materials Research Society, San Francisco, CA, 4-8 Apr. 1994
(Contract DE-AC05-84OR-21400)
(DE94-019332; CONF-940411-53) Avail: CASI HC A02/MF A01

Several compositions of the intermetallic alloy Ni3Al were examined with respect to: (1) their wetting of Al2O3; and (2) their energy absorption capability in Al2O3/Ni3Al laminates. Wetting is enhanced by small additions of carbon (e.g., 0.1 at. %), and bonding by additions of zirconium (e.g., 1 at. %). Chevron-notched laminate specimens were tested in three-point bending to assess the energy absorption due to the presence of a thin layer of Ni3Al. A nickel aluminide with the composition of Ni-22Al-1Zr-0.1C-0.1B was found to have a reasonable combination of wetting, adhesion and energy absorption. Interfacial bonding was found to be weak in all laminates. DOE

B4C-SIC REACTION-SINTERED COATINGS ON GRAPHITE PLASMA FACING COMPONENTS
P. G. Valentine, P. W. Trester, and J. Winter (Kernforschungsanlage, Juelich, Germany.) May 1994 24 p Presented at the 11th International Conference on Plasma Surface Interactions in Controlled Fusion Devices, Mito, Japan, 23-27 May 1994
(Contract DE-AC03-89ER-51114)
(DE94-019105; GA-A-21719; CONF-940580-19) Avail: CASI HC A03/MF A01

Boron carbide plus silicon carbide (B4C-SiC) reaction-sintered coatings for use on graphite plasma-facing components were developed. Such coatings are of interest in TEXTOR tokamak limiter-plasma interactions as a means of reducing carbon erosion, of providing a preferred release of boron for oxygen gettering, and of investigating silicon's effect on radiative edge phenomena. Specimens evaluated had: (1) either Ringsdorfwerke EK 98 graphite or Le Carbon Lorraine felt-type AEROLOR A05 CFC substrates; (2) multiphase coatings, comprised of B4C, Sic, and graphite; (3) nominal coating compositions of 69 wt.-% B4C + 31 wt.-% SiC; and (4) nominal coating thicknesses between 250 and 775 (mu)m. Coated coupons were evaluated by high heat flux experiments in the JUDITH (electron beam) test facility at KFA. Simulated disruptions, with energy densities up to 10 MJm(exp -2), and normal operation simulations, with power densities up to 12 MWm(exp -2), were conducted. The coatings remained adherent; at the highest levels tested, minor changes occurred, including localized remelting, modification of the crystallographic phases, occasional microcracking, and erosion. DOE

THE ROLE OF MICROCRACKING ON THE CRACK GROWTH RESISTANCE OF BRITTLE SOLIDS AND COMPOSITES
S. B. Biner 1994 10 p
(Contract W-7405-eng-82)
(DE95-001678; IS-M-806) Avail: CASI HC A02/MF A01

A set of numerical analyses of crack growth was preformed to elucidate the influence of microcracking on the fracture behavior of microcracking brittle solids and composites. The random nucleation, orientation and size effects of discrete nucleating microcracks and resulting interactions are fully accounted for in a hybrid finite element model. The results obtained from the finite element analysis are compared with the continuum description of the microcracking. Although continuum description can provide a reasonable estimation of shielding, it fails to resolve the details of micromechanism of toughening resulting from microcracking, since not every shielding event during the course of crack extension corresponds to an increase in the R-curve. Moreover, as seen in the composite cases, the local events leading to toughening behavior may not be associated with the microcracking even in the presence of a large population of microcracks. DOE

N95-21776# Oak Ridge National Lab., TN.
CREEP BEHAVIOR IN SiC WHISKER-REINFORCED ALUMINA COMPOSITE
H. T. Lin and P. F. Becher 1994 12 p Presented at the Engineering Foundation Conference on Plastic Deformation of Ceramics, Snowbird, UT, 7-12 Aug. 1994
(Contract DE-AC05-84OR-21400)
(DE95-001071; CONF-9408175-1) Avail: CASI HC A03/MF A01

Grain boundary sliding (often accompanied by cavitation) is a major contributor to compressive and tensile creep deformation in fine-grained aluminas, both with and without whisker-reinforcement. Studies indicate that the creep response of alumina composites reinforced with SiC whiskers can be tailored by controlling the composite microstructure and composition. The addition of SiC whiskers (less than 30 vol%) significantly increases the creep resistance of fine-grained (1-2 (mu)m) alumina in air at temperatures of 1,200 and 1,300 C. However, at higher whisker contents (30 and 50 vol%), the creep resistance is degraded due to enhanced surface oxidation reactions accompanied by extensive creep cavitation. Densification aids (i.e., Y2O3), which facilitate silica glass formation and thus liquid phase densification of the composites, can also result in degradation of creep resistance. On the other hand, increasing the matrix grain size or decreasing the whisker aspect ratio (increased whisker number density) results in raising the creep resistance of the composites. These observations not only explain the variability in the creep response of various SiC whisker-reinforced alumina composites but also indicate factors that can be used to enhance the elevated temperature performance. DOE

THE ROLE OF GRAIN BOUNDARY SLIDING ON CREEP DEFORMATION CHARACTERISTICS OF DISCONTINUOUS REINFORCED COMPOSITES
S. B. Biner 1994 15 p
(Contract W-7405-eng-82)
(DE95-001671; IS-M-807) Avail: CASI HC A03/MF A01

In this study, the grain boundary sliding behavior in discontinuous reinforced composites is investigated numerically. Results indicate that the stress enhancement factor for the composite is much larger than the one observed for the matrix material. In the composite, the increase in the strain rates as a result of grain boundary sliding occurs in a wider stress range in comparison to the matrix. It is shown that the experimentally observed large scale triple point grain boundary cavitation in the composites could occur as a result of large grain rotations resulting from grain boundary sliding and evolution of triaxial stress state. Also, the observed larger creep exponent values or stress dependent creep exponent values for the composites may not be explained solely by the mechanism of grain boundary sliding. DOE

The general emphasis for 1994 would be on increased software development, testing of subelements and design calculations. For these purposes, the constitutive law coding and development would be coordinated by Nick Aravas, and implemented in ABAQUS. The initial implementation would be the elastic/plastic model for MMC's with interface debonding developed in 1993 (Leckie). This would be extended in 1994 to include creep and some aspects of thermomechanical cycling. The code would be used for design calculations concerned with MMC rotors, actuators and vanes (Leckie). A plan is being formulated to collaborate with Pratt and Whitney to acquire MMC sub-elements representative of these components during 1994. Experimental tests on these subelements would be capable of providing a direct validation of the code capabilities. DTIC

RECENT DEVELOPMENTS IN LOW COST STABLE STRUCTURES FOR SPACE
T. C. Thompson, C. Grastataro, and B. G. Smith 1994 11 p Presented at the Advanced Materials for High Precision Detectors, Geneva, Switzerland, 28 Sep. 1994
(Contract W-7405-eng-36)
(DE95-000857; LA-UR-94-3144; CONF-9409222-1) Avail: CASI HC A03/MF A01

The Los Alamos National Laboratory (LANL) in partnership with Composite Optics Incorporated (COI) is advancing the development of low cost, lightweight, composite technology for use in spacecraft and stable structures. The use of advanced composites is well developed, but the application of an all-composite tracker structure has never been achieved. This paper investigates the application of composite technology to the design and fabrication of an all-composite spacecraft bus for small satellites, using technology directly applicable to central tracking in a high luminosity environment. The satellite program Fast On-Orbit Recording of Transient Events (FORTE) is the second in a series of satellites to be launched into orbit for the US Department of Energy (DOE). This paper will discuss recent developments in the area of low cost composites, used for either spacecraft or ultra stable applications in high energy physics (HEP) detectors. The use of advanced composites is a relatively new development in the area of HEP. The Superconducting Super Collider (SSC) spawned a new generation of Trackers which made extensive use of graphite fiber reinforced plastic (GFRP) composite systems. LANL has designed a structure employing new fabrication technology. This concept will lower the cost of composite structures to a point that they may now compete with conventional materials. This paper will discuss the design, analysis and proposed fabrication of a small satellite structure. Central tracking structures using advanced materials capable of operating in an adverse environment typical of that found in a high luminosity collider could use identical concepts. DOE

A TRANSMISSION ELECTRON MICROSCOPE CHARACTERIZATION OF SODIUM SULFATE HOT CORROSION OF SILICON CARBIDE FIBER-REINFORCED LITHIUM ALUMINOSILICATE GLASS-CERAMIC MATRIX COMPOSITE M.S. Thesis
Richard K. Hunt Sep. 1994 84 p
(AD-A286164) Avail: CASI HC A05/MF A01

Sodium sulfate hot corrosion of a SiC/lithium aluminosilicate (LAS) composite was studied using conventional transmission electron microscopy and selected area diffraction. Changes in the morphology, composition, and crystallography of the phases in the glass-ceramic matrix and the fiber/matrix interface were studied. Microchemical analysis using energy dispersive x-ray spectroscopy (EDS) was also performed on all phases detected. Three samples were studied: (1) as-received, (2) no salt coating and annealed in argon, and (3) sodium sulfate coated and annealed in oxygen. Both heat treatments were performed at 900 C for 100 hours. Sample (1) matrix was comprised of small stoichiometric grains of beta-spodumene (Li2O-Al2O3-4SiO2) and mullite (3Al2O3-2SiO2) in a high silica glass (88 wt% SiO_2 and 12 wt% Al_2O_3). The fiber/matrix interface consisted of an amorphous SiO_2 and graphitic carbon layer. Sample (2) showed a substantial decrease in mullite content with a concomitant increase in alumina content of the glass and crystalline phases. Sample (3) suffered considerable hot corrosion. DTIC

EFFECT OF LASER RADIATION ON CARBON FIBRE/EPOXY COMPOSITES [INVERKAN AV LASEREXPONERING PA KOLFIBERKOMPOSITER]
O. Dickman, O. Rydlund, and L. Svensson Jun. 1994 18 p In SWAHILI
(PB95-133526; FOA-A-20060-2.4) Avail: Issuing Activity (National Technical Information Service (NTIS))

The effect of laser radiation on carbon fiber/epoxy composites was studied. According to the literature exposure to intensities less than 1 kW/sq cm mainly degrade the matrix whereas intensities greater than 6-7 kW/sq cm degrade both matrix and fibers. The mechanical properties of carbon fiber composites are affected in a similar way as aluminum after exposure to laser. After laser exposure at high intensities the residual tensile strength of the carbon fiber composites was equal to a composite with a drilled hole. The experimental work essentially verified the literature survey at intensities 1 kW/sq cm. After CO_2-laser exposure (1 kW/sq cm) of quasi-isotropic carbon fiber composites no delamination outside the visible damaged area was detected. The reduction in tensile strength after laser exposure was in good agreement with the literature. NTIS

HIGH TEMPERATURE CORROSION AND CRACK GROWTH OF SIC/SIC AT VARIABLE OXYGEN PARTIAL PRESSURES
R. H. Jones, C. H. Henager, Jr., and C. F. Windisch, Jr. Jun. 1994 29 p Presented at the Japan-USA Seminar Development and Environmental Characteristics of New Materials, Mount Hood, OR, 7-9 Jun. 1994
(Contract DE-AC06-76RL-01830)
(DE94-018715; PNL-SA-24865; CONF-9406261-1) Avail: CASI HC A03/MF A01

Thermal gravimetric analysis (TGA) and subcritical crack growth (SCG) measurements of chemical-vapor-infiltrated (CVI)-SiC matrix, reinforced with Nicalon fibers and with a 1-micro m-thick C fiber/matrix interface, have been conducted at 1100 C over O_2/Ar mixtures ranging from 0.25% to 20.0% O_2. The TGA and interface recession measurements both gave linear reaction kinetics for O_2 concentrations of 2.0% or less and a reaction order of unity. Subcritical crack-growth measurements demonstrated that crack velocity in the stress intensity-independent Stage 2 regime increases with increasing O_2/Ar ratio. Also, The transition from Stage 2 to the stress intensity-dependent Stage 3 regime is shifted to lower stress intensities with increasing O_2/Ar ratio. A time-dependent crack-growth model that incorporates creep of the bridging SiC fibers and the removal of the C interfacial layer by oxidation successfully explains the subcritical crack-growth characteristics. THE INFLUENCE OF CHEMISTRY AND MICROSTRUCTURE ON THE FRACTURE TOUGHNESS OF V-V3SI IN-SITU COMPOSITES
G. A. Henshall, M. J. Strum, B. P. Bewlay (General Electric Co., Schenectady, NY.), and J. A. Sutliff (General Electric Co., Schenectady, NY.) 19 Aug. 1994 19 p Presented at the 2nd Fatigue and Fracture of Ordered Intermetallic Materials, Rosemont, IL, 3-6 Oct. 1994
(Contract W-7405-eng-48)
(DE94-018997; UCRL-JC-117630; CONF-9410203-1) Avail: CASI HC A03/MF A01

The room temperature fracture behavior is described for ductile-phase toughened V-V3Si in-situ composites produced by arc melting (AM), cold-crucible induction melting (IM), and cold-crucible directional solidification (DS). Composites were produced containing a wide range of microstructures, interstitial impurity contents, and volume fractions of the ductile V-Si solid solution phase, denoted (V). The fracture toughness of these composites generally increases as the volume fraction of (V) increases. For a given volume fraction of (V), the fracture toughness increases with decreasing 'effective' interstitial impurity content, (I)=(N)+1.3(O)+9(H). In eutectic composites, as (I) decreases from 1400 ppm (AM) to 400 ppm (IM), the fracture toughness increases from 10 to 20 MPa radical-m. The fracture toughness of the V-V3Si composites is further correlated with the mechanical properties of the component phases, SEM observations of the fracture surface characteristics, and electron back-scattering pattern measurements of the fracture facet crystallography. These correlations are discussed with respect to conventional ductile phase 'bridging' theories. DOE

FIBRE-REINFORCED HIGH-STRENGTH CONCRETE
Sirje Vares and Tarja Haekkinen Dec. 1993 93 p
(PB95-131942; VTT/PUB-160) Copyright Avail: Issuing Activity (National Technical Information Service (NTIS))

The publication comprises two experimental parts. In the first part, 14 different kinds of steel, polypropylene and polyacrylonitrile fibers are studied in order to make high-strength fiber-reinforced concrete. The effect of fiber type and volume on the load-deflection behavior of FRC is studied and discussed. When the steel fiber volume fraction is low there is usually no significant increase in the 'first crack' and flexural strengths, but the toughness of concrete can be significantly increased over that of plane matrix. The relatively high specific surface area of the polymer fibers (PAN and PP) affects advantageously the 'first crack' strength of the composite. In the second part of the report, the influence of aging on the load-deflection behavior of different kinds of FRC is studied. Different matrices reinforced with steel or polypropylene fiber were subjected to aging and temperature and humidity changes. High-strength fiber-reinforced concrete composites, especially those reinforced by steel fibers can withstand large variation of temperature and humidity without the performance of fibers being significantly weakened. The purpose of this work is to develop highly optically nonlinear CdS quantum dot-SiO_2 sphere composites useful for optical switching. The concept is to use these spheres in a BCC array formed from crystalline colloidal arrays. The spheres would normally be refractive index matched to the medium and light would freely transmit. At high light intensities the refractive index of the nonlinear spheres would diverge from the medium and the array would optically pop up to diffract away the high intensity light. The device would act as an optical limiter. Last year's report announced the development of a successful synthesis of these SiO_2-CdS sphere composites. During this report period, we refined our process in order to obtain more homogenous and monodisperse products. We have also extended this synthesis to produce several new materials. DTIC

The present invention relates to acoustic and vibration attenuation composite material, particularly to damping tiles of the Type VI class 1, suitable for use in aircraft, ship and submarine applications, that is inexpensive, does not result in an unacceptable weight penalty, and is conformable-in-place to complex curvatures. The present acoustic and vibration attenuation composite comprises a constraining layer of at least one ply of graphite fabric together with curable phenolic resin bonded to a viscoelastic layer. The thermal decomposition of methane shows significant potential as a process for the production of higher unsaturated and aromatic hydrocarbons when the extent of the reaction is limited. Preliminary experiments have shown that cooling the product and reacting gases as the reaction proceeds can significantly reduce or eliminate the formation of solid carbon and heavier (C10(+)) materials. Much work remains in optimizing the quenching process and this is one of the goals of this program. We will also study means to lower the temperature of the reaction as this will result in a more feasible commercial process due to savings realized in energy and material of construction costs. The use of free-radical generators and catalysts will be investigated as a means of lowering the reaction temperature thus allowing faster quenching. It is highly likely that such studies will lead to a successful direct methane to higher hydrocarbon process. DOE

Volatile organic chemicals are a class of pollutants which are regulated at very low levels by the EPA. Consequently a need exists as a part of site remediation efforts within DOE to develop technologies which will allow for the in situ monitoring of these chemicals. Resonance Raman spectroscopy is a potential technique to accomplish this if the resonance enhancement is sufficiently high. Carbon tetrachloride was selected as a test case. Measurements under resonance conditions at 248 nm showed an enhancement factor of 2 x 10(sup 4). Using this value an estimate of the sensitivity for both in situ and remote monitoring of CCl4 was made. It was concluded that resonance Raman could be used to detect these chemicals at levels of regulatory interest. Future effort directed towards the development of a suitable probe as well as a field-portable system would be desirable. Such effort could be directed towards the solution of a particular monitoring problem within a DOE waste remediation project. Once developed, however, it should be easily generalized to the analysis of other VOC's in other environments. DOE

In this paper, effects of Cu-ZSM-5 catalyst preparation on the activity of over-exchanged copper for NO decomposition are reported. The Cu-ZSM-5 catalysts were prepared by incorporating Cu(2+) cations into ZSM-5 zeolites from an aqueous cupric acetate solution adjusted to different pH values by adding either acetic anhydride or aqueous ammonia in the solution. The Cu(2+) exchange levels in creased with increasing pH level. STEM/EDX analysis identified CuO particles (5-6 nm) on the zeolite surface for the materials exchanged at pHgreater than 6. Conversion and kinetics measurements of NO decomposition to N2 over these catalysts showed that the over-exchanged copper was not active. Short-time wash with aqueous ammonia removed this copper. The catalyst activity correlated very well with the amount of copper remaining in the ZSM-5 channels. DOE

In the last Quarterly Technical Progress Report the authors reported the synthesis and (partial characterization) and SCR (Selective Catalytic Reduction of NO) activity for a delaminated Fe2O3 -pillared clay (Fe2O3)-PILC). The SCR activity for this PILC was substantially higher than that of the commercial-type V2O5 + WO3/TiO2 catalyst. During the past quarter, the authors first completed the characterization of the delaminated Fe2O3-PILC catalyst. Both physical characterization (micropore probing by adsorption and Moessbauer spectroscopy) and chemical characterization (by IR spectroscopy) were performed. Since the synthesis of this PILC sample was undertaken under a specific set of conditions and it is known that the PILC properties depend strongly on the synthesis conditions, they then proceeded to examine in a systematic manner the dependence of the catalytic properties of the PILC on its synthesis conditions. Four parameters in the synthesis were studied: Fe precursors, pH of the pillaring solution, concentration of the pillaring solution, and the starting clay. Finally, the effect of the Cr2O3 promoter on the SCR activity of the pillar clay was studied. Results are reported. DOE

CORRELATIONS BETWEEN SURFACE STRUCTURE AND CATALYTIC ACTIVITY/SELECTIVITY
D. W. Goodman Sep. 1994 19 p
(Contract DE-FG05-88ER-13954)
(DE94-019023; DOE/ER-13954/T2) Avail: CASI HC A03/MF A01

The primary focus of this research is to address those issues which are keys to understanding the relationship between surface properties and catalytic activity/selectivity. These issues also impact the understanding of the origins of the enhanced catalytic properties of mixed-metal catalysts. The experimental approach utilizes a microcatalytic reactor contiguous to a surface analysis system, an arrangement which allows in vacuo transfer of the catalyst from one chamber to the other. Surface techniques being used include Auger (AES), ultraviolet and X ray photoemission spectroscopy (UPS and XPS), temperature programmed desorption (TPD), low energy electron diffraction (LEED), high resolution electron energy loss spectroscopy (HREELS), infrared reflection absorption spectroscopy (IRAS), and scanning tunneling and atomic force microscopy (STM and AFM). This research program builds upon previous experience relating the results of single crystal kinetic measurements with the results obtained with supported analogs. As well, the authors are exploiting recent work on the preparation, the characterization, and the determination of the catalytic properties of ultra-thin metal and metal oxide films. Specifically, the program is proceeding toward three goals: (1) the study of the unique catalytic properties of ultrathin metal films; (2) the investigation of the critical ensemble size requirements for principal catalytic reaction types; and (3) the modelling of supported catalysts using ultra-thin planar oxide surfaces. GLOBAL EQUIVALENCE RATIO CONCEPT AND THE PREDICTION OF CARBON MONOXIDE FORMATION IN ENCLOSURE FIRES
W. M. Pitts Jun. 1994 172 p See also PB89-200091 and PB90-209602
(PB94-207511; NIST/Mono-179) Avail: CASI HC A08/MF A02; SOD HC

This report summarizes investigations of the formation of carbon monoxide (CO) in enclosure fires -- the most important factor in fire deaths. It contains the first complete review and analysis of the literature available on the global equivalence ratio (GER) concept. The results of a number of recent investigations (including work during the past fiscal year) which were either supported by the BFRL Grants Program or carried out in-house are then discussed. Based on the findings, two completely new mechanisms for the formation of CO, in addition to the quenching of a fire plume by rich upper layer covered by the GER concept, are identified. The first involves reaction of rich flame gases with air which is entrained directly into the high-temperature upper layer of an enclosure fire. The second results from the pyrolysis of oxygenated polymers (such as wood) which are located in a rich, high-temperature upper layer. The findings of these studies form the basis of an analysis which yields the conditions for which use of the GER concept is appropriate for predicting CO formation in enclosure fires. NTIS

MERCURY CAPTURE IN BENCH-SCALE ABSORBERS
C. D. Livengood, H. S. Huang, M. H. Mendelsohn, and J. M. Wu 1994 11 p Presented at the 10th Annual Coal Preparation, Utilization and Environmental Control Contractors Conference, Pittsburgh, PA, 18-21 Jul. 1994
(Contract W-31-109-eng-38)
(DE94-016910; ANL/ES/CP-83739; CONF-940780-3) Avail: CASI HC A03/MF A01

This paper gives a brief overview of research being conducted at Argonne National Laboratory on the capture of mercury by both dry sorbents and wet scrubbers. The emphasis in the research is on development of a better understanding of the key factors that control the capture of mercury. Future work is expected to utilize that information for the development of new or modified process concepts featuring enhanced mercury capture capabilities. The results and conclusions to date from the Argonne research on dry sorbents can be summarized as follows: lime hydrates, either regular or high-surface-area, are not effective in removing mercury; mercury removals are enhanced by the addition of activated carbon; mercury removals with activated carbon decrease with increasing temperature, larger particle size, and decreasing mercury concentration in the gas; and chemical pretreatment (e.g., with sulfur or (CaCl2)) can greatly increase the removal capacity of activated carbon. Preliminary results from the wet scrubbing research include: no removal of elemental mercury is obtained under normal scrubber operating conditions; mercury removal is improved by the addition of packing or production of smaller gas bubbles to increase the gas-liquid contact area; polysulfide solutions do not appear promising for enhancing mercury removal in typical FGC systems; stainless steel packing appears to have beneficial properties for mercury removal and should be investigated further; and other chemical additives may offer greatly enhanced removals. The U.S. Department of Energy has conducted programs of research and development in hydrogen and related technologies since 1975. The current program, conducted in accordance with the DOE Hydrogen Program Plan FY 1993--FY 1997 published in June 1992, establishes program priorities and guidance for allocating funding. The core program, currently under the Office of Energy Management, supports projects in the areas of hydrogen production, storage, and systems research. At an annual program review, each research project is evaluated by a panel of technical experts for technical quality, progress, and programmatic benefit. This Proceedings of the April 1994 Hydrogen Program Review compiles all research projects supported by the Hydrogen Program during FY 1994. For those people interested in the status of hydrogen technologies, we hope that the Proceedings will serve as a useful technical reference. Individual reports are processed separately. DOE

NATURAL GAS CLEANUP: EVALUATION OF A MOLECULAR SIEVE CARBON AS A PRESSURE SWING ADSORBENT FOR THE SEPARATION OF METHANE/NITROGEN MIXTURES
R. W. Grimes Jun. 1994 16 p
(Contract DE-FC21-86MC-11076)
(DE94-012263; DOE/MC-11076/3829) Avail: CASI HC A03/MF A01

This report describes the results of a preliminary evaluation to determine the technical feasibility of using a molecular sieve carbon manufactured by the Takeda Chemical Company of Japan in a pressure owing adsorption cycle for upgrading natural gas (methane) contaminated with nitrogen. Adsorption tests were conducted using this adsorbent in two, four, and five-step adsorption cycles. Separation performance was evaluated in terms of product purity, product recovery, and sorbent productivity for all tests. The tests were conducted in a small, single-column adsorption apparatus that held 120 grams of the adsorbent. Test variables included adsorption pressure, pressurization rate, purge rate and volume, feed rate, and flow direction in the steps from which the product was collected. Sorbent regeneration was accomplished by purging the column with the feed gas mixture for all but one test series where a pure methane purge was used. The ratio between the volumes of the pressurization gas and the purge gas streams was found to be an important factor in determining separation performance. Flow rates in the various cycle steps had no significant effect. Countercurrent flow in the blow-down and purge steps improved separation performance. Separation performance appears to improve with increasing adsorption pressure, but because there are a number of interrelated variables that are also effected by pressure, further testing will be needed to verify this. The work demonstrates that a molecular sieve carbon can be used to separate a mixture of methane and nitrogen when used in a pressure swing cycle with regeneration by purge. Further work is needed to increase product purity and product recovery. DOE

FTIR SPECTROSCOPY FOR THE DETERMINATION OF WATER IN CORROSIVE GASES

R. K. Rowe, B. R. Stallard, L. H. Espinoza (New Mexico Univ., Albuquerque, NM.), and T. M. Niemczyk (New Mexico Univ., Albuquerque, NM.) 1994 8 p Presented at the Microcontamination 1994, San Jose, CA, 5-6 Oct. 1994
(Contract DE-AC04-94AL-85000)
(DE94-014658; SAND-94-1554C; CONF-9410132-2) Avail: CASI HC A02/MF A01

Internal corrosion in semiconductor gas delivery systems may lead to increased particle counts in downstream fabrication tools and to catastrophic failure of the delivery system itself. The problem is particularly acute since, once the corrosion begins, it becomes a moisture reservoir to further damage the system. To keep gas systems as moisture free as possible semiconductor manufacturers employ drying filters, usually located just after the source of the process gas. Even so, the piping for corrosive gases may need to be rebuilt every few years. Careful monitoring of the moisture in the process gases can provide valuable information about the state of the gas handling system and its effect on the process integrity. Presently there are several technologies costing $50K or less that are capable of detecting trace water vapor as low as 50 ppb in N2. However, no one type of instrument has achieved universal acceptance. In particular, all have limited compatibility with corrosive gases such as HCl and HBr. The goal of this project is to develop an in-line instrument based on infrared spectroscopy for this purpose. Earlier results leave no doubt that FTIR spectroscopy can be successfully used for trace water detection. However, important questions regarding optimal data analysis and instrument design are not yet fully answered. It is the goal of this research effort to answer these questions and to incorporate the findings into a prototype device suitable for commercialization. DOE

COMPUTER PROGRAM FOR CALCULATION OF COMPLEX CHEMICAL EQUILIBRIUM COMPOSITIONS AND APPLICATIONS. PART 1: ANALYSIS

Sanford Gordon and Bonnie J. McBride Oct. 1994 58 p
(NASA-RP-1311; E-8017; NAS 1.61:1311) Avail: CASI HC A04/MF A01

This report presents the latest in a number of versions of chemical equilibrium and applications programs developed at the NASA Lewis Research Center over more than 40 years. These programs have changed over the years to include additional features and improved calculation techniques and to take advantage of constantly improving computer capabilities. The minimization-of-free-energy approach to chemical equilibrium calculations has been used in all versions of the program since 1967. The two principal purposes of this report are presented in two parts. The first purpose, which is accomplished here in part 1, is to present in detail a number of topics of general interest in complex equilibrium calculations. These topics include mathematical analyses and techniques for obtaining chemical equilibrium; formulas for obtaining thermodynamic and transport mixture properties and thermodynamic derivatives; criteria for inclusion of condensed phases; calculations at a triple point; inclusion of ionized species; and various applications, such as constant-pressure or constant-volume combustion, rocket performance based on either a finite- or infinite-chamber-area model, shock wave calculations, and Chapman-Jouguet detonations. The second purpose of this report, to facilitate the use of the computer code, is accomplished in part 2, entitled 'Users Manual and Program Description'. Various aspects of the computer code are discussed, and a number of examples are given to illustrate its versatility. Author

SELECTIVE METHANE OXIDATION OVER PROMOTED OXIDE CATALYSTS

K. Klier, R. G. Herman, Chunlei Shi, and Qun Sun Jun. 1994 10 p
(Contract DE-FG21-92MC-29228)
(DE94-012270; DOE/MC-29228/3837) Avail: CASI HC A02/MF A01

Experimental work aiming at developing active catalysts for selective oxidation of methane to methanol was started in this quarter. Some of the experiments used a double catalyst bed design and with H2O as cofeed. The first catalyst bed, which serves as CH3 radical generator, was chosen to be 1 wt % SO4(exp -2)/Sr/La2O3, as this catalyst exhibits remarkable activity and selectivity at lower temperature (500 C to 550 C). A few transition metal oxides were used as the second catalyst bed to react with CH3 to form CH3O(exp -1)M(exp +1) species, which was then hydrolyzed to form CH3OH. It was found that unsupported metal oxides ZrO2, Y2O3, SrO, Fe2O3, MnO2, Cr2O3, CaO, and MgO did not produce CH3OH between 430 C and 600 C when used as the only catalysts, while MoO3 supported on silica produced CH3OH in the temperature range of 430 C to 480 C under the current single-bed reactor configuration. However, when the double-bed configuration was used with the 1 wt % SO4(exp -2)/Sr/La2O3 as the first methyl radical generating catalyst bed, CH3OH was observed when ZrO2 and Y2O3 we re used as the second bed catalysts. Preliminary quantitative analysis showed that the ability of producing CH3OH was in the order of unsupported Y2O3 greater than unsupported ZrO2 greater than MoO3 on silica. For all of these cases, the CH3OH space time yield was within a dozen grams per kilogram catalyst per hour. DOE

SAFE CONDITIONS FOR CONTACTING NITRIC ACID OR NITRATES WITH TRI-N-BUTYL PHOSPHATE (TBP)

M. Hyder Jan. 1994 24 p
(Contract DE-AC09-89SR-18035)
(DE95-001243; WSRC-TR-94-059) Avail: CASI HC A03/MF A01

In response to a request from DOE-SR, the current state of knowledge of the reactions between tri-n-butyl phosphate (TBP) and aqueous nitrate solutions is critically reviewed, and recommendations are made for the safe operation of SRS separations equipment in which this combination of chemicals may be present. The existing limits for evaporation are validated. Guidelines are presented for cases in which general limits do not apply. The rate of reaction between nitric acid and TBP appears to be controlled by the rate of TBP hydrolysis. The hydrolysis reaction produces dibutyl phosphate and n-butanol. The hydrolysis rate is a strong function of temperature, and becomes very fast at temperatures in the range 130 to 150 C. The resulting n-butanol is volatile at high temperatures, boiling at 117.5 C, but is also subject to exothermic oxidation by nitric acid or nitrates. If oxidation occurs before the n-butanol evaporates, the heat of oxidation may exceed local cooling by convection. The resulting heating will further accelerate the reaction, leading to an energetic runaway and possibly (in confined systems) an explosion. Extensive experiments and practice have shown that in a well-mixed and well-vented aqueous system such as an evaporator, at moderate acidities and temperatures below 130 C, the heat of reaction is adequately removed by vaporization of steam. In general, the heating will be so slow that natural processes provide adequate cooling at temperatures below 80 C. Above this temperature, care should be taken to ensure that adequate cooling is available for the amount of TBP that may be present. Experiments suggest that in well-ventilated systems n-butanol evaporation and convective cooling are sufficient to control the reaction at temperatures up to 120 C. DOE

ORIENTATION STUDIES OF POLYOLEFINS BY IR-DICHROISM

T. Tjaeder 1994 39 p
(PB95-104386; ISBN-951-22-2080-6) Avail: CASI HC A03/MF A01

The investigation of the structural changes in polymers upon drawing is relevant with respect to their mechanical properties. Although several methods like wide-angle x-ray scattering, birefringence and refractive index measurements exist to analyze the structure of semicrystalline polymers, infrared polarized spectroscopy is the most useful and practical method that yields quantitative information about molecular orientation of the polymer chains in the crystalline and the amorphous phase separately. Infrared dichroism offers also special advantages where multiphase systems such as polymer blends are concerned. The aim of the paper is to present shortly the basics of IR-dichroism and to introduce this method for polyethylene (PE) and polypropylene (PP). Also some hints are given about the practical performance of the method. NTIS

FERROCYANIDE SAFETY PROJECT DYNAMIC X-RAY DIFFRACTION STUDIES OF SODIUM NICKEL FERROCYANIDE REACTIONS WITH EQUIMOLAR NITRATE/NITRITE SALTS

J. N. Dodds (Washington State Univ., Pullman, WA.) and W. J. Thomson (Washington State Univ., Pullman, WA.) Jul. 1994 39 p
(Contract DE-AC06-76RL-01830)
(DE94-017396; PNL-10050) Avail: CASI HC A03/MF A01

Dynamic X-ray Diffraction (DXRD) has been to used to identify and quantify the solid state reactions that take place between sodium nickel ferrocyanide, Na2NiFe(CN)6, and equimolar concentrations of sodium nitrate/nitrite, reactions of interest to the continued environmental safety of several large underground waste storage tanks at the Hanford site in eastern Washington. The results are supportive of previous work, which indicated that endothermic dehydration and melting of the nitrates take place before the occurrence of exothermic reactions that being about 300 C. The DXRD results show that a major reaction set at these temperatures is the occurrence of a series reaction that produces sodium cyanate, NaCNO, as an intermediate in a mildly exothermic first step. In the presence of gaseous oxygen, NaCNO subsequently reacts exothermally and at a faster rate to form metal oxides. Measurements of the rate of this reaction are used to estimate the heat release. Comparisons of this estimated heat release rate with heat transfer rates from a hypothetical 'hot spot' show that, even in a worst-case scenario, the heat transfer rates are approximately eight times higher than the rate of energy release from the exothermic reactions. DOE

TESTS OF DIELECTRIC MODEL DESCRIPTIONS OF CHEMICAL CHARGE DISPLACEMENTS IN WATER

G. J. Tawa and L. R. Pratt 1994 12 p Presented at the 208th American Chemical Society National Meeting, Washington, DC, 21-26 Aug. 1994
(Contract W-7405-eng-36)
(DE94-007530; LA-UR-94-431; CONF-940813-1) Avail: CASI HC A03/MF A01

A dielectric model of electrostatic solvation is applied to describe potentials of mean force in water along reaction paths for (1) pairing of sodium and/or chloride ions; (2) the symmetric S(sub N)2 exchange of chloride in methylchloride; (3) nucleophilic attack of formaldehyde by hydroxide anion. For these cases simulation and XRISM results are available for comparison. The accuracy of model predictions varies from spectacular to poor. It is argued that: (1) dielectric models are physical models, even though simplistic and empirical; (2) their successes suggest that second-order perturbation theory is a physically sound description of free energies of electrostatic solvation; and (3) the most serious deficiency of the dielectric models lies in the definition of cavity volumes. Second-order perturbation theory should therefore be used to refine the dielectric models. These dielectric models make no attempt to assess the role of packing effects but for salvation of classical electrostatic interactions the dielectric models appear to perform as well as the more detailed XRISM theory. ASSESSMENT OF LIQUEFACTION AND PYROLYSIS SYSTEMS

Y. Solantausta, J. Diebold, D. C. Elliott, T. Bridgwater, and D. Beckman 1994 206 p Prepared in cooperation with National Renewable Energy Lab., Golden, CO; Battelle Pacific Northwest Labs., Richland, WA; Aston Univ., Birmingham, England; and Zeton, Inc., Burlington, Ontario
(PB95-129797; VTT/RN-1573) Copyright Avail: Issuing Activity (National Technical Information Service (NTIS))

This report summarizes the results of the International Energy Agency (IEA) Biomass Agreement Pyrolysis/Liquefaction activity from 1989 to 1991. A summary of the developments of state of the art direct biomass pyrolysis and liquefaction technology is presented. Results are presented of a technoeconomic analysis of a wood pyrolysis to gasoline process based on experimental work at the National Renewable Energy Laboratory, USA, and of a straw liquefaction to fuel oil process based on experimental work at Manchester University, UK. The potential for chemicals from biomass is also considered. A standard technoeconomic procedure was used for the analysis, with a plant size of 1,000 dry t/d biomass feed. Sensitivity cases covering feedstock costs, capital cost variation and plant capacity are also presented. NTIS

INVESTIGATION OF SYNGAS INTERACTION IN ALCOHOL SYNTHESIS CATALYSTS

1994 12 p
(Contract DE-FG22-93MT-93010)
(DE94-018784; DOE/MT-93010/2) Avail: CASI HC A03/MF A01

This work presents the progress of the work done during the second quarter on 'Investigation of syngas interaction in Alcohol Synthesis Catalysts'. The essential results have been presented at the second annual Historically Black Colleges and Universities/Private Sector/Energy Research and Development Technology Transfer Symposium. The primary objective of this project is to examine the relations between the catalytic and magnetic properties of the copper-cobalt higher alcohol synthesis catalysts. Since extensive catalytic results are available from the studies of the IFP group, the authors have undertaken to investigate the magnetic character by studying the Zero Field Nuclear Magnetic Resonance (ZFNMR) of cobalt and hysterisis character of the Cu/Co catalysts. The authors have examined three different aspects of these catalysts: (1) effect of metal ratio; (2) effect of method of preparation; and (3) effect of selectivity. DOE

ACTINIDE(IV) AND ACTINIDE(VI) CARBONATE SPECIATION STUDIES BY PAS AND NMR SPECTROSCOPIES

D. L. Clark, S. A. Ekberg, D. E. Morris, P. D. Palmer, and C. D. Tait Sep. 1994 62 p
(Contract W-7405-eng-36)
(DE94-016957; LA-12820-MS) Avail: CASI HC A04/MF A01

Pulsed-laser photoacoustic spectroscopy (PAS) and Fourier-transform nuclear magnetic resonance (NMR) spectroscopy were used to study speciation of actinide(IV) and actinide(VI) ions (Np, Pu, Am) in aqueous carbonate solutions as of pH, carbonate concentration, actinide content, and temperature. PAS focused on Pu(IV) speciation. Stability fields on a pH (8.4 to 12.0) versus total carbonate content (0.003 to 1.0 M) plot for dilute Pu(IV) carbonate species ((Pu)(sub tot) = 1 mM) were mapped. Four plutonium species, with absorption peaks at 486, 492, 500, and 512 nm were found. Loss of a single carbonate ligand does not account for the difference in speciation for the 486 and 492 nm absorption peaks, nor can any of the observed species be identified as colloidal Pu(IV). NMR data have been obtained for UO2(2+), PuO2(2+) and AmO2(2+). This report focuses on results for PuO2(2+). The ligand exchange reaction between free and coordinated carbonate on the PuO2(CO3)3(sup 4-) systems has been examined by variable temperature C-13 NMR spectroscopy. In each of the six different PuO2(CO3)3(sup 4-) samples, two NMR signals are present, one for the free carbonate ligand and one for the carbonate ligand coordinated to a paramagnetic plutonium metal center. The single C-13 resonance line for coordinated carbonate is consistent with expectations of a monomeric PuO2(CO3)3(sup 4-) species in solution. A modified Carr-Purcell-Meiboom-Gill NMR pulse sequence was used for determining of ligand exchange parameters for paramagnetic actinide complexes. Eyring analysis at standard conditions provided activation parameters of (Delta)H = 38 KJ/M and (Delta)S = -60 J/K for the plutonyl triscarbonate system, suggesting an associative transition state for the plutonyl(VI) carbonate complex self-exchange reaction. DOE

FABRICATION AND TESTING OF A SILICON IMMERSION GRATING FOR INFRARED SPECTROSCOPY
P. J. Kuzmenko, D. R. Ciarlo, and C. G. Stevens 25 Jul. 1994 12 p Presented at the Annual Meeting of the Society of Photo-Optical Instrumentation Engineers, San Diego, CA, 24-29 Jul. 1994
(Contract W-7405-eng-48)
(DE94-017173; UCRL-JC-117810; CONF-940723-15) Avail: CASI HC A03/MF A01

Recent advances in silicon micromachining techniques (e.g. anisotropic etching) allow the fabrication of very coarse infrared echelle gratings. When used in immersion mode, the dispersion is increased proportionally to the refractive index. This permits a very significant reduction in the overall size of a spectrometer while maintaining the same resolution. We have fabricated a right triangular prism (30 x 60 x 67 mm) with a rectangular entrance face (30 x 38 mm) from silicon with a grating etched into the face of the hypotenuse. The grating covers an area of 32 mm by 64 mm and has a 97.5 PM periodicity with a blaze angle of 63.4 deg. The groove surfaces are very smooth with a roughness of a few manometers. Random defects in the silicon are the dominant source of grating scatter (approximately 12% at 3.39 (mu)m). We measure a grating ghost intensity of 1.2%. The diffraction peak is quite narrow, slightly larger than the Airy disc diameter at F/12. However due to wavefront aberrations, perhaps 15-20% of the diffracted power is in the peak with the rest distributed in a diameter roughly five times the Airy disc. DOE

NOVEL CATALYSTS FOR METHANE ACTIVATION Quarterly Report No. 7, 1 Apr. - 30 Jun. 1994
A. S. Hirschon, H. J. Wu, R. Malhotra, and R. B. Wilson Sep. 1994 34 p
(Contract DE-AC22-92PC-92112; SRI Proj. 4069)
(DE95-002639; DOE/PC-92112/T7) Avail: CASI HC A03/MF A01

Fullerenes are a recently discovered allotrope of carbon that have been found to possess unusual properties, some of which may be ideal for methane activation. This project is designed to evaluate these carbon based materials for conversion of methane into higher hydrocarbons. The project is divided into three technical tasks: task 1 deals with the synthesis and characterization of the fullerenes and fullerene soots; task 2 with the testing of the catalysts; and task 3 with the evaluation of the results and technical reporting requirements. The results and accomplishments for this quarter are summarized below: soots were prepared either by extraction in toluene or sublimation of the lower fullerenes (such as C 60/C70); a fullerene soot was prepared by adding C60 to an extracted soot; fullerene soot was doped with platinum and nickel by incipient wetness techniques, and a nickel fullerene complex was synthesized using organometallic techniques; soot from three manufactures were tested for methane activation and found to exhibit small but notable differences in reactivity; increasing the surface area of soots by partial oxidation with CO2 did not cause significant changes in the reactivities; the effect of the extraction and sublimation of C60 /C70 was determined to be minor; the effect of added C60 to an extracted MER soot was determined to be beneficial; acetylene black was tested and found to have higher activity and lower selectivity than a Norit-A carbon; and nickel and platinum doped soots were found to be more active than the undoped soots. VISIBLE AND NEAR-IR SPECTROSCOPIC STUDIES OF UC1(4) IN A BASIC AMBIENT TEMPERATURE MELT: THE OBSERVATION OF A POSSIBLE GEOMETRIC DISTORTED UC1(6)(EXP 2-) SPECIES AND THE EVIDENCE FOR THE HYDROGEN-BOND IN THE MELT
S. Dai, L. M. Toth, G. D. DelCul, and D. H. Metcalf 1994 2 p Presented at the 185th Electrochemical Society Meeting, San Francisco, CA, 22-27 May 1994
(Contract DE-AC05-84OR-21400)
(DE94-017764; CONF-940529-24) Avail: CASI HC A01/MF A01

Since high temperatures can lead to broadening of absorption spectra, ambient temperature chloride melts were used; the system used was AlCl3-1-ethyl-3-methyl-imidazolium chloride (EMIC). The uv-visible spectrum of UCl4 in basic melt had many peaks with the most intense (triplet) ones around 2000 nm, similar to these at high temperature and indicating the same species. The electronic transition is allowed by a static rather than a vibronic mechanism. The central peak in the UCl6 (sup 2-) spectrum indicates distortion of geometry from the O(sub h) symmetry by the solvent medium. Very strong hydrogen bonding between UCl6(sup 2-) and solvent EMI is suggested. DOE

ANGLE RESOLVED AUGER ELECTRON SPECTROSCOPY: AN ALTERNATE TOOL FOR IDENTIFYING ELECTRONIC EXCITATION PROCESSES IN SOLIDS Technical Report, Sep. 1993 - Oct. 1994
David E. Ramaker, R. A. Fry, and Y. U. Idzerda Sep. 1994 13 p
(Contract N00014-94-I-0331)
(AD-A285375; TR-67) Avail: CASI HC A03/MF A01

Angle resolved Auger electron spectroscopy (ARAES) is shown to be a useful tool for obtaining unique electronic structure information and identifying satellite excitation processes in solids. Although relatively unexplored, ARAES is an attractive tool which may complement the more conventional energy resolved AES. The ARAES method is successful because the diffraction patterns exhibited in ARAES at fixed energy are strongly dependent on the l-wave of the emitted electron and its magnetic alignment, and each Auger process is generally dominated by a different single l-wave. Potential applications for elucidating satellite excitation processes (resonant excitation, shakeup/shakeoff, and backscattering), one- and two-center decay processes, and electronic structure (directional valence bonds and orbital magnetic moments) at surfaces are discussed. ELECTROSPRAY IONIZATION FOURIER TRANSFORM ION CYCLOTRON RESONANCE MASS SPECTROMETRIC STUDY OF SINGLY AND DOUBLY CHARGED ORGANOMETALLIC COMPLEXES Technical Report, Aug. 1993 - Feb. 1994
R. Ramanathan, D. E. Richardson, J. R. Eyler, C. Stacey, and G. H. Kruppa 27 May 1994 42 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-87-J-1248)
(AD-A279899; TR-44-ONR) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

An external source electrospray ionization (ESI) Fourier transform ion cyclotron resonance (FTICR) mass spectrometer has been used to study the organometallic complexes Ag2(DPM)2(BF4)2 (where DPM = bis-diphenylphosphino-methane), Ag2(DPM)3(BF4)2 and Ru(II)(bp)3(PF6)2 (where bpy = 2,2'-bipyridyl). The high mass resolution and accurate mass assignment of parent and collisionally induced dissociation (CID) fragment ions provided structural information on these organometallic complexes. CID in the capillary/skimmer region and inside the FTICR analyzer cell were performed on these complexes and results from each type of experiment were compared. Important fragmentation pathways and reaction types, including bond cleavage, ligand loss, and ligand substitution were identified. DTIC

COMBUSTION-RELATED STUDIES USING WEAKLY BONDED COMPLEXES
Robert A. Beaudet Oct. 1994 20 p
(Contract DE-FG03-89ER-14053)
(DE95-002801; DOE/ER-14053/T6) Avail: CASI HC A03/MF A01

Binary van der Waals complexes and bimolecular reactions relevant to combustion have been prepared and studied using tunable IR diode laser spectroscopy. The complexes were prepared in supersonic expansions using pulsed slit nozzles. In the first phase, geometries and other molecular properties were determined from vibration-rotation spectra. Two complementary classes of binary complexes were investigated. The first involves molecular oxygen (e.g., O2-HCN, O2-HF, Ob 2-HCl, O2-HBr, O2-HI and O2- hydrocarbons) and the corresponding photoinitiated reactions. The authors obtained spectra O2-HCl in helium. Such complexes involving triplet state molecules have not been studied, and the spectra are more complex than those whose constituents are simple singlet molecules. These complexes are interesting because upon photodissociating the hydride portion, the reaction of H with O2 via the vibrationally excited HO2(+) intermediate can be studied: BrH-O2 + hv(193 nm) (yields) Br-H-O2 (yields) Br + HO2 (+) (yields) Br + OH + O. Also, the authors attempted to study a unique set of species involving oxygen atoms and small molecules such as HF, HCl, HBr, HI, HCN and simple hydrocarbons. A carrier gas was seeded with SO2 and the second constituent O(P-3) is prepared by 193 nm S O2 photodissociation. Because the reactions of O(P-3) with small molecules had a significant activation energies, the complexes survive the expansion: e.g., O + HCl has E(sub act) = 22 kJ/mol, and the oxygen atom will lie in a shallow well just outside the barrier. Unfortunately, the beam temperature after the photolysis was too warm to preserve van der Waals complexes. The authors also developed IR diode laser spectroscopy as a probe to study bimolecular reactions in a pulsed slit supersonic expansion. DOE

NONLINEAR SPECTROSCOPY OF MULTICOMPONENT DROPLETS AND TWO- AND THREE-DIMENSIONAL MEASUREMENTS IN FLAMES Final Technical Report, 1 Feb. 1991 - 31 Jan. 1994
Richard K. Chang and Marshall B. Long 31 Mar. 1994 36 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Grant AF-AFOSR-0150-91; AF Proj. 2308)
(AD-A279945; AFOSR-94-0320TR) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Significant progress has been made in the following two research areas: (A) Nonlinear spectroscopy of micrometer-sized multicomponent droplets; and (B) Two- and three-dimensional scalar and velocity mapping. (A) Chemical species and physical properties of multicomponent liquid droplets in a spray combuster can be determined by a nonintrusive in-situ optical diagnostics techniques. A brief summary of the research accomplishments in the three areas related to the nonlinear optical interactions inside micron-sized droplets and the applications of such spectroscopy to determine the chemical and physical properties of the droplets: (1) Model for nonlinear optical processes in droplets; (2) fluorescence seeding of simulated Raman scattering (SRS) of the Minority Species; and (3) Detection of slight shape distortion by spectroscopic means. (B) A review of the progress in our multi-dimensional scalar and velocity measurements in turbulent flames is also given. Among the accomplishments during the funding period are the following: (1) Scalar field measurements of differential diffusion effects in turbulent flows; (2) Development of a digital particle image velocimetry (PIV) technique for velocity field measurements in reacting and nonreacting flows; (3) Combination of the new digital PIV technique with previously developed fluorescence imaging techniques to allow simultaneous vector and scalar imaging in turbulent flames; and (4) Development of new mixture fraction imaging techniques for studying turbulent nonpremixed hydrocarbon flames. MAPPING CLOSURES FOR TURBULENT COMBUSTION Final Report, 15 Feb. 1991 - 14 Feb. 1994
Stephen B. Pope 19 Apr. 1994 12 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Grant AF-AFOSR-0184-91; AF Proj. 2308)
(AD-A279995; AFOSR-94-0323TR) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The overall objective of the research program was to develop and test an improved model for the process of molecular diffusion in turbulent reactive flows. In application to turbulent combustion, a major shortcoming of existing models is that they are non-local in composition. A model has been developed, based on the construction of a Euclidean minimum spanning tree (EMST). This model is inspired by the mapping closure, and reduces to it in the case of a single composition. In general, the model is asymptotically local, and hence overcomes a major flaw in previous models.

The model has been tested for decaying scalars in isotropic turbulence and for a mean scalar gradient. Additionally, studies have been made of stochastic Lagrangian mode's for turbulent reactive flows; and an exact expression has been obtained for the probability density function of temperature (or other random quantities) in statistically stationary turbulence. QUANTUM CHEMICAL STUDY OF RARE GAS/HALIDE INTERACTIONS AS A MODEL FOR HIGH ENERGY DENSITY MATERIAL. 1: TRANSITION PROPERTIES IN HCl Final Report, Sep. 1990 - 1991
George F. Adams and Cary F. Chabalowski Nov. 1994 27 p
(DA Proj. 1L1-61102-AH-43)
(AD-A285988; ARL-TR-609) Avail: CASI HC A03/MF A01

As an extension of our earlier studies of rare gas (Rg) atomic and molecular interactions (Chablowski et al. 1989), we begin this preliminary theoretical treatment of the Rg-halide interactions by studying the electronic states and electronic transition probabilities between electronic states in HCl. This information will be necessary to understand the results from future studies where we will explicitly include xenon atoms with the HCl, producing electronic states that are mixtures of xenon and HCl. It is also of interest to determine what effect the use of effective core potentials has on predicting known experimental molecular properties as well as properties predicted by other ab initio studies. Quantum chemical calculations are performed on the ground and excited states of HCl, including Effective Core Potentials (ECPs) (Wadt and Hay 1985), State Averaged-Complete Active Space MCSCF (SA-CASSCF) for generating state averaged molecular orbitals (MOs), and configuration interaction (CI) calculations to obtain the final electronic state wave functions. COMPUTATIONAL EVALUATION OF THE FEASIBILITY OF NITRATING PRECURSORS TO C12N12O12
Peter Politzer and M. Edward Grice 20 Oct. 1994 7 p
(Contract N00014-91-J-4057)
(AD-A285976; TR-71) Avail: CASI HC A02/MF A01

In order to determine the feasibility of nitrating the immediate precursors of 1, we have computed the average local ionization energies on their surfaces and compared their minimum values to those of mono-, di- and trinitrobenzene. Our results indicate that there is a reasonable likelihood of being able to nitrate the precursors of C12N12O12. DTIC

GAS-PHASE GENERATION OF ZINC SULFIDE PARTICLES USING A SINGLE-SOURCE PRECURSOR
Mark J. Hampden-Smith, D. Zeng, A. Datye, Q. Powell, and A. Gurav 6 May 1994 32 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-91-J-1258)
(AD-A279700; TR-13) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Nanometer-sized (20 to 40 nm) ZnS particles were produced in a flow reactor by gas-phase reaction of the single-source precursor Zn(S2CNEt(sub2))(sub2)TMEDA), where TMEDA = tetramethylethylenediamine. The precursor was prepared by reaction of the dimer, (Zn(S2CNEt(sub2))(sub 2))(sub 2), with two equivalents of TMEDA. The product was isolated in quantitative yield and characterized by a variety of spectroscopic techniques and by single-crystal X-ray diffraction in the solid state. Transparent, colorless prisms of empirical formula C16H36N4S4Zn crystallized by cooling a warm (60 C), saturated toluene solution to room temperature, in the orthorhombic crystal system, space group P2(1)2(1)2(1) with unit cell dimensions a = 8.785(1) A, b = 11.611(2) A, c = 23.321(2) A, z = 4, with R = 4.64%, Rw = 5.32% for 3262 independent reflections where F is greater than 3.0 sigma(F). The structure of Zn(S2CNEt(sub2))(sub2)(TMEDA) was monomeric and distorted octahedral in the solid state. The precursor was evaporated into the gas phase and reacted in a hot-wall reactor at temperatures of 500, 600, and 700 C resulting in the formation of ZnS particles X-ray diffraction showed phase-pure ZnS particles with crystallite sizes of 15 - 25 nm at all temperature studied. Thermogravimetric analysis, elemental analysis, and transmission electron microscopy suggested that the particles also contained sulfur derived from the precursor. DTIC

DETERMINATIONS OF PHASE TRANSITIONS IN NYLON 6-12, NYLON-6, POLYVINYL CHLORIDE AND POLYETHYLENE TEREPHTHALATE BY POSITRON ANNIHILATION SPECTROSCOPY Ph.D. Thesis [DETERMINACION DE LAS TRANSICIONES DE FASE EN NYLON 6,12, NYLON-6, POLI(CLORURO DE VINILO) Y POLI(TEREFTALATO DE ETILENO) POR ESPECTROSCOPIA DE ANIQUILACION DEL POSITRON]
M. J. CamachoReyes 1993 90 p In SPANISH
(DE94-629992; INIS-MF-13924) Avail: CASI HC A05/MF A01 (US Sales Only)

Positron annihilation lifetime spectroscopy (PALS) was used to investigate the phase transitions, mainly the glass transition, of poly(vinyl chloride) (PVC), Nylon-6,12, Nylon-6, poly(ethylene terephthalate) during the thermal treatment of these polymers. The longest lived component lifetime and intensity, indicative of ortho-Positronium pick-off exhibit thermal dependencies that can be attributed to the anticipated free volume changes associated with structural transitions. Positron lifetime measurements were performed using an E G and G Ortec standard fast-fast coincidence system. Three spectra were collected at each temperature, each consisting of a peak height of approximately 25000 counts. The resulting spectra were consistently modeled with a three component fit using the computer program PATFIT. For nylon-6,12, nylon-6, PVC systems three transitions were obtained in both tau-3 and I-3 as a function of temperature. Changes in the slope of the curves appear for both parameters, these could be attributed to T(sub g1), T(sub g2) and T(sub c), respectively. In the case of PET analysis two transitions were obtained as is shown by the variations of tau-3 as a function of the heating temperature. These transitions can be attributed to T(sub g1) and T(sub g2). Similar changes can be observed for I-3 in relation with temperature. Glass transition behavior was evident in the lifetime behavior of polymers. Increases in slope of the lifetime temperature plots were interpreted free-volume cavity expansion as temperature is increased. The intensity responses in the vicinity of the upper glass transition were consistent with the association of this transition with the reduction of crystalline constraint of segmental mobility in the amorphous phase. TIME-RESOLVED ANALYTICAL METHODS FOR LIQUID/SOLID INTERFACES
Joel M. Harris 31 Oct. 1994 10 p
(Contract DE-FG03-93ER-14333)
(DE95-002255; DOE/ER-14333/T1) Avail: CASI HC A02/MF A01

A number of chemical phenomena that occur at the boundaries between insulating solids and liquids (adsorption, partition, monolayer self-assembly, catalysis, and chemical reactions) are important to energy-related analytical chemistry. These phenomena are central to the development and understanding of chromatographic methods, solid-phase extraction techniques, immobilized analytical reagents, and optical sensors. The goal of this program, therefore, is to develop surface-sensitive spectroscopies by which chemical kinetics at liquid/solid interfaces can be observed on time scales from nanoseconds to seconds. In the second year of this program, the authors used temperature-jump relaxation measurements to monitor adsorption/desorption kinetics at liquid/solid interfaces using Joule heating to compare the adsorption of ions from solution onto C1- and C4-derivatized silica surfaces. They completed a study of rate of migration of covalently-attached ligands on silica surfaces; from the temperature-dependence of the migration, the large energy barrier to migration was estimated. Surface heterogeneity of adsorption sites on silica was characterized by time-resolve fluorescence, and the chemical origins investigated by Si(sup 29) NMR spectroscopy. Surface-enhanced Raman and fluorescence spectroscopies were modified to study adsorption and binding to silica surfaces. Molecular dynamics simulations were started to help better understand kinetic barriers to adsorption; ESR probe measurements were launched to measure and compare the chain mobility of silica-attached alkyl ligands. AN IMPROVED AND FACILE METHOD FOR THE SYNTHESIS OF 1,1-BIS(4-HYDROXYPHENYL) 2-PHENYLETHYLENE AND ITS DERIVATIVES
B. Shafii, R. W. Atcher, and E. R. DeSombre (Chicago Univ., Chicago, IL.) 1994 12 p
(Contract W-31-109-eng-38)
(DE95-001125; ANL/CHM/PP-75382) Avail: CASI HC A03/MF A01

The synthesis of 1,1-bis(4-hydroxyphenyl)-2-phenylethylene, which is of biological interest, has been reported by several authors in the past. In this article an improved method is introduced. Different (and commercially available) starting materials are adopted. Also a protective group which is easily attached and removed is used. This procedure provides milder reaction conditions and better yields while the number of steps involved in the synthesis of the compound are reduced. Furthermore, the reactions are clean and formation of byproducts which lead to poorer yields are avoided. DOE

GORDON RESEARCH CONFERENCE ON PHYSICAL ELECTROCHEMISTRY Final Report
Hector D. Abruna 30 Mar. 1994 15 p Conference held in New London, NH, 3-7 Aug. 1992
(Contract N00014-92-J-1493)
(AD-A286545) Avail: CASI HC A03/MF A01

The Gordon Research Conference on Physical Electrochemistry was held from August 3-7, 1992 at the Colby Sawyer School in New London, New Hampshire. The program combined researchers in the mainstream of electrochemistry, as well as individuals, who, while not electrochemists, work in areas of relevance to the study and understanding of electrochemical phenomena. The choice of speakers represented a combination of established researchers as well as some younger investigators. This mix gave the conference a sense of what is of current relevance as well as what areas will be forthcoming. The main themes covered in the program were: the use of scanned probe microscopies to the study of electrochemical phenomena with emphasis on STM and AFM. Spectroscopic techniques in the study of electrochemical interfaces with emphasis on synchrotron radiation; Theoretical aspects of the structure of water next to surfaces, electron transfer and superconductivity and their relation to electrochemical phenomena; studies on Langmuir-Blodgett and self-assembling monolayers. ELECTROCHEMICAL IMPEDANCE SPECTROSCOPY OF TRIVALENT CHROMIUM PRE-TREATED ALUMINUM ALLOY Progress Report
Vinod S. Agarwala and Dieter W. Beckert 14 Dec. 1993 21 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A280093; NAWCADWAR-94014-60) Avail: CASI HC A03

A chemical conversion coating on aluminum alloys was developed using a trivalent chromium bath. Electrochemical impedance spectroscopy (EIS) was made to characterize the corrosion resistant properties of the surface films formed. The results showed a 10 to 100 fold increase in the polarization resistance of the surface films compared to the untreated aluminum alloy. These electrochemical results compared well with the corrosion behavior in salt spray tests. The trivalent chromium-treated surfaces showed no corrosion for up to 200 hours in 5% salt spray. A post-treatment with an oxidizer even further raised the coating's resistance due to an improved corrosion protection. DTIC

INERT GAS PURIFICATION AND MEASURING OXYGEN PARTIAL PRESSURE IN GAS MIXTURES WITH EMF METHOD BASED ON SOLID ELECTROLYTE CELL
Iikka Isomaeki 1994 31 p
(ISSN 0785-5168)
(PB95-127767; TKK-V-B90; ISBN-951-22-1951-4) Avail: CASI HC A03/MF A01

Inert atmospheres are often needed in metallurgical and chemical high-temperature experiments to prevent the sample from undesired reactions such as oxidation. Argon gas is readily available and thus the most commonly used medium for this purpose, so the first task is to secure that this gas is free from unwanted impurities such as oxygen, water and carbon dioxide. For example, AGA Oy supplies three different qualities of argon: (1) Ar 4.8 containing max. 20 ppm impurities; (2) Ar 5.0 containing max, 10 ppm impurities; and (3) Ar 6.0 containing max. 1 pppm impurities. Even if gas which contains max. 1 ppm impurities is used, the actual impurity content of argon in a furnace can be much higher. Gas is easily contaminated if plastic tubes are used. Therefore, it is better to use metallic tubes with brazed or threaded joints. Gas purification can be performed by passing gas through devices between the gas container and the furnace, so it is possible to reach at least the ppb level of impurities. In the report some methods to remove impurities from inert gas, especially from Ar, are discussed, as also the technique for building up the gas tubing, and methods to measure the partial pressure of oxygen, utilizing solid electrolyte based EMF measurements in the experimental atmosphere. HIGH MAGNETIC FIELD GLOW DISCHARGE IONIZATION SOURCE Technical Report, Jul. 1993 - May 19
K. L. Goodner, C. Dejsupa, C. M. Barshick, and J. R. Eyler 27 May 1994 5 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-87-J-1248)
(AD-A279972) Avail: CASI HC A01

We have modified our 'internal' electrospray source, which operates inside the high magnetic field associated with Fourier transform ion cyclotron resonance (fticr) mass spectrometry, to allow it to serve as a glow discharge (GD) ionization source. Quite reasonable ion signals are obtained with this source, in spite of the fact that the glow discharge ionization is taking place at a magnetic field of about 1.8 tesla. This corresponds to a field at least a factor of 25 higher than has ever been used with glow discharge sources before. One example of an analysis of the (60)Ni(+) signal in a NIST 661 stainless steel signal. Signal-to-noise calculations for the top trace yield a limit of detection of 38 ppm for the peak at m/z 60. The predominant ion is (56)Fe(+), arising from the high concentration of iron in the steel. DTIC

EXCESS ENERGY AND STRUCTURAL DEPENDENCE OF THE RATE OF ENERGY REDISTRIBUTION DURING THE PHOTODISSOCIATION OF IODOTOLUENES
John E. Freitas, Hyun J. Hwang, and M. A. El-Sayed 27 May 1994 39 p
(Contract N00014-89-J-1350)
(AD-A279997; TR-77) Avail: CASI HC A03/MF A01

The ortho (2-), meta (3-), and para (4-) iodotolunes (C7H7I) are photodissociated at 266 nm and 30.4 nm and studied with state-selective one-dimensional photo-fragment translational spectroscopy. Angular velocity, and translational energy distributions are obtained for the ground state I((2)p(3/2)) and spin-orbit excited state I*((2)P(1/2)) iodine atoms produced photodissociation. As has been observed in iodobenzene, the ground state I channel observed in each isomer of iodotoluene exhibits both a prompt alkyl iodide-like dissociation channel following a parallel excitation to the alkyl iodide (3)Q(zero)(n, sigma*) repulsive state and curve crossing to the (1)Q(1)(n,sigma*) state, and a slower, indirect dissociation channel following a competitive excitation to aromatic charge transfer (pi, pi*) predissociate excited states at both 266 nm and 304 nm. The I* channel observed at both 266 nm and 304 nm for each isomer results from prompt dissociation resulting from parallel absorption to an alkyl iodide type (3)Q(zero)(n, sigma*) state. The rapid I and I* dissociative channels observed for each isomer are found to exhibit strong dependence on the excess excitation. This is discussed in terms of the increase in the density of the vibrational states of the toluene ring. Dissociation times and rates of internal energy redistribution (IER) from the slow dissociative channel (Beta) are estimated for each isomer. For 2-iodotoluene, the rate of IER for the slow I channel increases from 20 kcal/mol-ps at 304 nm to 30 kcal/mol-ps at 266 nm, while the rates of IER for 3- and 4-iodotoluene (16 kcal/mol-ps and 15 kcal/mol-ps, respectively) remain unchanged as the photon energy is increased. TECHNOLOGY DEVELOPMENT FOR COBALT F-T CATALYSTS
A. H. Singleton 31 May 1994 208 p
(Contract DE-AC22-92PC-92108)
(DE94-017363; DOE/PC-92108/T6) Avail: CASI HC A10/MF A03

The goal of this project is the development of a commercially viable, cobalt-based Fischer-Tropsch (F-T) catalyst for use in a slurry bubble column reactor. Cobalt-based catalysts have long been known as being active for F-T synthesis. They typically possess greater activity than iron-based catalysts, historically the predominant catalyst being used commercially for the conversion of syngas based on coal, but possess two disadvantages that somewhat lessen its value: (1) cobalt tends to make more methane than iron does; and (2) cobalt is less versatile with low H2/CO ratio syngas due to its lack of water-gas shift activity. Therefore, the major objectives of this work are: (1) to develop a cobalt-based F-T catalyst with low (less than 5%) methane selectivity; (2) to develop a cobalt-based F-T catalyst with water-gas shift activity; and (3) to combine both these improvements into one catalyst. It will be demonstrated that these catalysts have the desired activity, selectivity, and life, and can be made reproducibly. Following this experimental work, a design and a cost estimate will be prepared for a plant to produce sufficient quantities of catalyst for scale-up studies. DOE

FIRE EXPERIMENTS IN A TWO DIMENSIONAL RACK STORAGE: BRANDFORSK-PROJECT 701-917
Haukur Ingason 1993 25 p Sponsored by Swedish Research Board, Lund Univ., and SP
(ISSN 0284-5172)
(PB95-131538; SP-RAPP-1993:56; ISBN-91-7848-441-3) Avail: CASI HC A03/MF A01

Flame heights and air flows in a two dimensional rack storage were investigated. The width of the vertical flue is found to be the predominant geometrical parameter controlling the flue flow. The mass flow rate increases nearly linearly with the width. Variation of the horizontal flue heights was found to have negligible effects on the vertical flue flow. For a certain vertical flue width, the mass flow rate is found to be nearly constant independent of the heat output. Experimental results indicate a linear relationship between the flame height and the ratio of heat output to the vertical flue width. A ratio of entrained air to the stoichiometric air requirements at the flame tip is found to be 7.5. Experiments were carried out using inert boxes and a diffusion propane line burner located at the bottom of the rack. The rack was 0.59 m long and between 1.14 m and 1.34 m in height (4 boxes). The size of the rack is about 1/3 of what can be expected in a real rack storage. NTIS

LINEAR AND NONLINEAR SPECTROSCOPY WITH THE TUNABLE AC SCANNING TUNNELING MICROSCOPE
S. J. Stranick, L. A. Bumm, M. M. Kamna, and P. S. Weiss 10 Oct. 1994 15 p
(Contract N00014-91-J-1630)
(AD-A285751; TR-20) Avail: CASI HC A03/MF A01

The tunable microwave frequency AC scanning tunneling microscope (ACSTM) has opened the possibility of recording local spectra and local chemical information on insulator surfaces much as the conventional STM has done for metals and semiconductors. We describe the various types of spectroscopies that can be performed with the ACSTM. These include linear spectroscopies where the amplitude at the modulation frequency is measured as well as nonlinear spectroscopies utilizing the amplitudes of the harmonics of the modulation frequency generated in the tunneling junction. Spectroscopy in the microwave frequency range also enables heretofore unrealizable measurements on conducting substrates such as the rotational spectroscopy of a single adsorbed molecule. DTIC

AROMATICS OXIDATION AND SOOT FORMATION IN FLAMES
J. B. Howard 1994 4 p
(Contract DE-FG02-84ER-13282)
(DE95-001803; DOE/ER-13282/10) Avail: CASI HC A01/MF A01

This project is concerned with the kinetics and mechanisms of aromatic oxidation and soot and fullerenes formation in flames. The objective of the aromatics oxidation work is to identify and measure the concentration of important intermediates and products in benzene oxidation, and to determine reaction mechanisms and kinetics properties consistent with the behavior seen in flames. The research on soot formation is concerned primarily with the particle inception stages, but the work includes study of soot structure at all stages of growth in order to obtain mechanistic information from evidence of growth steps recorded in the structure of the particles. The ultimate objective is to understand how nascent soot particles are formed from high molecular weight compounds, including the roles of planar and curved PAH and the relationship between soot and fullerenes. The objective of the proposed research on fullerenes is to develop a more comprehensive understanding of the range of fullerenes formed in flames, the nature of the precursor species, and the mechanisms and kinetics of the formation reactions. LIEKKI COMBUSTION TECHNOLOGY
M. Hupa 1994 140 p
(DE95-700233; KTM/E-B-153) Avail: CASI HC A07/MF A02

The five-year LIEKKI combustion research program (1988-1992) was oriented towards research serving the development of energy production techniques based on combustion. The program was divided into the following five research areas: (1) modeling of combustion processes, (2) combustion chemistry, (3) diagnostics and analytics, (4) pressurized combustion, and (5) applied projects. The first three of these research areas involved theoretical as well as experimental laboratory work carried out at universities or various public research organizations. This research aimed at better understanding of the combustion process and associated phenomena without commitment to any particular combustion technique. The fourth research area was focused at studies associated with the pressurized fluidized bed, using two pilot-size test rigs. The main target in the fifth research area was to reduce the combustion flue gas emissions at existing conventional plants, by affecting the various factors of the combustion process. In the five-year period, the program included 92 projects, whose total costs amounted to FIM 142 million. DOE

CHARACTERIZATION OF POLY(TETRAFLUOROETHYLENE) SURFACES BY ATOMIC FORCE MICROSCOPY: RESULTS AND ARTIFACTS
A. J. Howard, R. R. Rye, and K. Kjoller (Digital Instruments, Inc., Santa Barbara, CA.) 1994 12 p Presented at the Atomic Force Scanning Tunneling Microscopy Symposium, Natick, MA, 7-9 Jun. 1994
(Contract DE-AC04-94AL-85000)
(DE95-000742; SAND-94-1129C; CONF-9406268-1) Avail: CASI HC A03/MF A01

The surfaces of virgin and chemically etched poly(tetrafluoroethylene) (PTFE) have been studied using atomic force microscopy (AFM) in both contact and tapping modes. While attempting to perform AFM in contact mode on this relatively soft polymeric material, tip-induced imaging artifacts (presumably due to blunt tips and tip-to-surface interactions) were identified when the results were compared to scanning electron microscopy (SEM) surface images. When subsequent AFM imaging was performed in tapping mode it was apparent that these tip-induced artifacts were eliminated. Comparable tapping mode AFM and SEM images were obtained for even the highly porous, unstable surface that results from sodium naphthalenide etching of PTFE. AFM imaging in tapping mode of virgin and etched PTFE surfaces shows the three-dimensional character of the etched surface necessary for mechanical interlocking and resultant strong adhesion. DOE

ANODIC OXYGEN-TRANSFER ELECTROCATALYSIS AT IRON-DOPED LEAD DIOXIDE ELECTRODES Ph.D. Thesis
Jianren Feng 1994 134 p
(Contract W-7405-eng-82)
(DE95-001653; IS-T-1713) Avail: CASI HC A07/MF A02

The research illustrated in this thesis was performed under the guidance of Professor Dennis C. Johnson beginning in March 1987. Chapter 2 concentrates on the development and electrocatalytic properties of iron-doped (beta)-PbO2 films on noble-metal substrates. Chapter 3 focuses attention on the preparation and characterization of iron-doped (beta)-PbO2 films on titanium substrates (Fe-PbO2/Ti). Chapter 4 discusses anodic evolution of ozone at Fe-PbO2/Ti electrodes. Chapter 5 describes electrochemical incineration of p-benzoquinone (BQ) at Fe-PbO2/Ti electrodes. In addition, the Appendix includes another published paper which is a detailed study of (alpha)-PbO2 films deposited on various types of stainless steel substrates. DOE

NOVEL ABSORPTION DETECTION TECHNIQUES FOR CAPILLARY ELECTROPHORESIS Ph.D. Thesis
Y. Xue 27 Jul. 1994 158 p
(Contract W-7405-eng-82)
(DE95-001673; IS-T-1696) Avail: CASI HC A08/MF A02

Capillary electrophoresis (CE) has emerged as one of the most versatile separation methods. However, efficient separation is not sufficient unless coupled to adequate detection. The narrow inner diameter (I.D.) of the capillary column raises a big challenge to detection methods. For UV-vis absorption detection, the concentration sensitivity is only at the (mu)M level. Most commercial CE instruments are equipped with incoherent UV-vis lamps. Low-brightness, instability and inefficient coupling of the light source with the capillary limit the further improvement of UV-vis absorption detection in CE. The goals of this research have been to show the utility of laser-based absorption detection. The approaches involve: on-column double-beam laser absorption detection and its application to the detection of small ions and proteins, and absorption detection with the bubble-shaped flow cell. GRADIENT INDEX LENSES FROM SOL-GEL LAYERING Annual Report, 1 Jul. 1993 - 30 Jun. 1994
John D. Mackenzie 30 Jun. 1994 7 p
(Contract F49620-93-1-0364)
(AD-A285649; AFOSR-94-0657TR) Avail: CASI HC A02/MF A01

The research proposed here is based on the principle of the density gradient column. A liquid (A) of low density is continuously mixed into a liquid (B) of higher density while B is allowed to flow slowly down the wall of a glass cylinder. The feed rate of A is equal to the flow rate of mixture. Thus, a gradient density column is formed. Such columns have been used to measure the density of semiconductors to five (5) significant figures. The gradient is stable for many months at room temperature. We proposed to use this method to prepare gradient index (GRIN) lenses from gels with large axial gradients. The chemical compositions of two sols are selected based on considerations of solubility between the sols; differences in refractive index, density, expansion coefficient and densification temperatures between resulting oxides. TECHNICAL AND ECONOMIC EVALUATION OF NATURAL GAS BASED SYNTHESIS GAS PRODUCTION TECHNOLOGIES
J. Sogge, T. Stroem, and T. Sundset 15 Feb. 1994 261 p
(PB95-130597; STF21-A93106) Avail: Issuing Activity (National Technical Information Service (NTIS))

This report describes a conceptual study that has been done on technical and economic evaluation of different synthesis gas production technologies. A literature review on synthesis gas processes and a status on the different technologies and their licensors have been worked out. In addition, 9 different front-end synthesis gas processes supporting a 2500 MTPD methanol plant have been considered: Conventional steam reforming, noncatalytic partial oxidation (POX), catalytic partial oxidation (CPO), autothermal reforming, combined reforming, combined reforming with prereforming, gas heated reforming (GHR), combined autothermal reforming (CAR) and Kellogg reforming exchanger system (KRES). Capital and operating costs were calculated for each process, and sensitivity analysis performed on important cost parameters. The results show that among the commercial processes, autothermal and combined reforming have the best economy with 17-18% lower total cost than steam reforming. Among the new technologies, GHR and KRES both show even better economy, with approximately 22-23% lower total cost than steam reforming. NTIS

PROPERTIES OF AGED METAL TRITIDES

G. T. McConville, D. A. Menke, D. S. West, and C. M. Woods 22 Jun. 1994 15 p
(Contract DE-AC04-88DP-43495)
(DE95-001787; MLM-3799) Avail: CASI HC A03/MF A01

The interaction of tritium with metals is made complex by two phenomena. The first is that the beta decay in the metal produces He-3. The helium moves to form bubbles. This report shows that growth of the bubbles produces a two-stage swelling of the metal that comes first from the appearance of the helium and second from the relaxation of the lattice disorder. The second phenomena is the steady state ion and free radical concentration in the tritium over gas that interacts with impurities on the metal surface. This report shows that the reaction rates are much faster than for normal hydrogen cleaning. DOE

CLUSTER REACTIONS: AN APPROACH TO UNDERSTANDING THE FUNDAMENTALS OF HETEROGENEOUS CATALYSIS

A. W. Castleman, Jr. and Evan Pugh 1994 10 p
(Contract DE-FG02-92ER-14258)
(DE95-002947; DOE/ER-14258/2) Avail: CASI HC A02/MF A01

The physical basis for catalysis is not well understood and the motivation for this ongoing research is to provide a basis for unraveling the role which composition, morphology and electronic states have on the functioning of catalysts for various classes of reactions. The work during the first two and one-half year grant period has focused on unsupported clusters of selected composition, charge state, and size. Research has proceeded along three general lines of inquiry: (1) investigation of the reactivity of these cluster materials and determination of the influence of their charged state; (2) determination of the kinetics of association (adsorption) of various reactants and unraveling the mechanisms of certain oxidation reactions known to be catalyzed on metal cluster alloys, oxides and carbides; and (3) thermochemical measurement of the absorption of gaseous species onto alloy and metal oxide and carbide cluster systems. The authors have pursued the role of metal and metal-oxide clusters, and the charge states of these, as they function to influence the reactions of adsorbed species including ammonia, alcohols, water, NO(x), as well as CO and hydrogen. Evidence has been obtained that small positively charged nickel clusters function to catalyze reactions between adsorbed CO and hydrogen. In supportive studies, they have investigated the clustering of ammonia, methanol and water to nickel clusters of varying size. These studies, in conjunction with density functional calculations which are in progress, provide insight into cluster structures and knowledge of adsorption energies. DOE

OPERATOR'S MANUAL FOR THE MULTISTATION OFFGAS ANALYSIS SYSTEM

A. B. Hayes and J. A. Basford 10 Oct. 1994 18 p
(Contract DE-AC05-84OS-21400)
(DE95-002060; Y/DW-1332) Avail: CASI HC A03/MF A01

The Multistation Offgas Analysis System (MOAS) is a fully automated instrument which can independently measure the gases emitted by up to four samples in containers heated in ovens. A mass spectrometer is used to determine accurately their flow rates. There are six interconnected high vacuum pumping stations, one for each of the sample containers, one for the mass spectrometer, and one for the calibrated leaks which are used to calibrate the mass spectrometer. Quadstar 421(trademark) is the software package marketed by Balzers, the manufacturer of the mass spectrometer. This software used by MOAS is a combination of Quadstar 421(trademark), special routines, called sequences in the Balzers nomenclature, and compiled programs that controls MOAS. Tests are run repeatedly on each of the four oven stations, while stations that are not ready, or do not have a sample are skipped. While the computer is sitting idle between tests, the software monitors the vacuum system. If necessary, the software will shut down a pumping station that is not operating correctly. The status of pumping stations and tests, filenames for data and oven temperatures are stored on disk, so the software can recover from a power failure. The operator can use the software to start or stop testing, load parts, perform calibrations as necessary, and start up or shut down pumping stations. The software aids in routine functions, such as changing an ion gauge, by performing the required valve actuations automatically, and checking the pressure readings and turbopump speeds as necessary. The computer takes mass spectrometer sensitivity calibration data automatically, every week at 12:00AM on Sunday. An operator does not need to be present for these calibrations. The calibration data are saved and may be used or deleted by the operator at a later date. DOE

PRODUCTION OF S2F10, S2OF10 AND S2O2F10 BY SPARK DISCHARGES IN SF6*

I. Sauers, S. M. Mahajan (Tennessee Technological Univ., Cookeville, TN.), and R. A. Cacheiro (Tennessee Univ., Knoxville, TN.) 1994 8 p Presented at the 7th International Symposium on Gaseous Dielectrics, Knoxville, TN, 24-28 Apr. 1994
(Contract DE-AC05-84OR-21400)
(DE95-001421; CONF-940414-5) Avail: CASI HC A02/MF A01

Measurements have been made of the spark yield of S2F10 and S2OF10 as a function of O2 and H2O concentration. In addition the formation of S2O2F10 is reported. The spark yield of S2F10 is reduced when either oxygen or water is added to SF6. On the other hand the yield of S2OF10 is increased when either oxygen or water is added, oxygen having the greater effect. A simple model is presented based on a common SF5 precursor to S2F10 and S2OF10 showing good agreement with the yields of both byproducts in O2/SF6 and H2O/SF6 mixtures. The yield of S2F10 is found to be greatest when the spark chamber is very dry and the electrodes are well conditioned. DOE

TEMPORAL EVOLUTION OF TURBULENCE/CHEMISTRY INTERACTIONS IN LIFTED, TURBULENT-JET FLAMES

R. W. Schefer, M. Namazian (Altex Technologies Corp., Santa Clara, CA.), E. E. J. Filtopoulos (Altex Technologies Corp., Santa Clara, CA.), and J. Kelly (Altex Technologies Corp., Santa Clara, CA.) 1994 17 p Presented at the 25th International Symposium on Combustion, Irvine, CA, 31 Jul. - 5 Aug. 1994
(Contract DE-AC04-76DP-00789)
(DE95-002481; SAND-94-8730C; CONF-940711-18) Avail: CASI HC A03/MF A01

Flame ignition, extinction and reignition that control flame stability are time dependent. Two-pulse images of the instantaneous CH/CH4 distributions, with a variable time delay between images, were used to study the temporal evolution of turbulence/chemistry interactions in lifted, turbulent CH4-jet flames. The jet exit velocity was 21 m/s (jet exit Reynolds number 7,000). The results emphasize interactions between turbulence structure and the flame that lead to large fluctuations in experimental flame lift-off height. The results show that the flame envelope curves around semi-organized, large-scale vortical structures formed along the periphery of the jet. Interactions between these vortical structures and the flame cause excessive stretch that leads to local flame extinction. Extinction occurs on both the downstream edges of the structures and on the upstream sides. Once the flame is extinguished by a vortical structure, the flame stabilization point can be carried significant distances downstream by the vortex. The return to an upstream stabilization location occurs through turbulent premixed flame propagation. The images show upstream propagation of the flame within the image plane. Evidence also exists for the importance of flame propagation in the azimuthal direction normal to the image plane. DOE

RAMAN SPECTRA OF MOCVD-GROWN FERROELECTRIC PbTiO3 THIN FILMS
Z. C. Feng (National Univ. of Singapore,, Singapore.), B. S. Kwak (Georgia Inst. of Tech., Atlanta, GA.), and A. Erbil (Georgia Inst. of Tech., Atlanta, GA.) 1993 13 p Presented at the Fall Meeting of the Materials Research Society (MRS), Boston, MA, 29 Nov. - 3 Dec. 1993
(Contract DE-AC05-84OR-21400)
(DE94-018964; CONF-931108-110) Avail: CASI HC A03/MF A01

Lead titanate (PbTiO3) has been grown on a variety of substrates by using the metalorganic chemical vapor deposition (MOCVD) technique. The substrates employed included Si, GaAs, MgO, fused-quartz, sapphire, and KTaO3. Raman spectra from these heterostructures are presented. All of the films exhibited the strong, narrow spectral features characteristic of PbTiO3 perovskite-oxide crystals and indicative of high crystalline quality. The temperature behavior of the Raman modes, including the so-called 'soft-mode,' was studied. A 'difference-Raman' technique was used to distinguish the contributions of the PbTiO3 film and the KTaO3 single-crystal substrate. DOE

SURFACE INSPECTION USING FOURIER TRANSFORM INFRARED SPECTROSCOPY
G. L. Powell (Martin Marietta Energy Systems, Inc., Oak Ridge, TN.), N. R. Smyrl (Martin Marietta Energy Systems, Inc., Oak Ridge, TN.), D. M. Williams (Martin Marietta Energy Systems, Inc., Oak Ridge, TN.), H. M. Meyers, III (Martin Marietta Energy Systems, Inc., Oak Ridge, TN.), T. E. Barber (Oak Ridge Inst. for Science and Education, TN.), and M. Marrero-Rivera (Oak Ridge Inst. for Science and Education, TN.) Aug. 1994 10 p Presented at the Aerospace Environmental Technology Conference, Huntsville, AL, 10-11 Aug. 1994
(Contract DE-AC05-84OS-21400)
(DE95-001699; Y/DZ-1113/R1; CONF-9408174-2) Avail: CASI HC A02/MF A01

The use of reflectance Fourier transform infrared (FTIR) spectroscopy as a tool for surface inspection is described. Laboratory instruments and portable instruments can support remote sensing probes that can map chemical contaminants on surfaces. Detection limits under the best of conditions are in the subnanometer range (i.e., near absolute cleanliness), excellent performance is obtained in the submicrometer range, and useful performance may exist for films tens of microns thick. Identifying and quantifying contamination such as mineral oils and greases, vegetable oils, and silicone oils on aluminum foil, galvanized sheet steel, smooth aluminum tubing, and gritblasted 7075 aluminum alloy and D6AC steel are described. The ability to map in time and space the distribution of oil stains on metals is demonstrated. Techniques for quantitatively applying oils to metals, subsequently verifying the application, and nonlinear relationships between reflectance and the quantity of oil are discussed. DOE

THE ENERGETICS AND DYNAMICS OF FREE RADICALS, IONS, AND CLUSTERS
T. Baer 1994 12 p
(Contract DE-FG05-88ER-13950)
(DE94-018101; DOE/ER-13950/T3) Avail: CASI HC A03/MF A01

The structure and energetics of free radicals, ions, and clusters have been investigated by photoelectron photoion coincidence (PEPICO) and analyzed with the aid of ab initio molecular orbital and statistical theory (RRKM) calculations. The two major themes are the quantitative analysis of unimolecular reactions with no adjustable parameters, and the study of cluster ion dissociation processes. Molecules (or free radicals) were prepared in a molecular beam so that they are translationally and vibrationally cold. The translational temperature was calculated from the measured time of flight (TOF) peak width, while the vibrational temperature was determined from the shift in the dissociation onset. Free radicals are produced by pyrolysis in the nozzle, and subsequent cooling of the free radicals is demonstrated. Ion dissociation rates in the range from 10(exp 4) to 10(exp 7)/sec are measured from the asymmetric TOF distribution. This method was used to measure the dissociation rates of a number of cold and warm ions, among them HCl (DCl) loss from C2H5Cl(+) (C2D5Cl(+)), a reaction that proceeds via tunneling. The analysis of the butene ion dissociation provided information about the role of angular momentum in dissociation reactions. This dissociative ionization of ethylene clusters demonstrated that ethylene dimerions rearranged to butene ions prior to dissociation. Finally, a new value for the t-butyl ion heat of formation, which corrects a 15 kJ/mol error in the previous value, was obtained from the 0 K breakdown diagram of t-butyl iodide. DOE

A VISUAL CELL FOR MEASURING THE SOLUBILITY OF PROGRADE SOLUBLE SALTS IN WATER AT HIGH TEMPERATURES AND PRESSURES

R. C. Moore, J. M. Simonson, and R. E. Mesmer Oct. 1994 15 p
(Contract DE-AC05-84OR-21400)
(DE95-002058; ORNL-6829) Avail: CASI HC A03/MF A01

An apparatus has been constructed for measuring the solubility of prograde soluble salts in water at high temperatures and pressures. The apparatus consists of a visually accessible cell thermostated in a rocking furnace. The apparatus allows for rapid, accurate solubility measurements for temperatures over 650 K and pressures up to 170 bars. The cell was constructed of platinum with sapphire windows and gold seals for corrosion resistance. A 3x telescope is used to observe the phase change in the cell. A key feature of the cell is the ability to control the system pressure. A section of small bore platinum tubing is used to connect the cell to an external pressure source. The tubing can remain open to the pressure source or be sealed off during a measurement. To minimize equilibration times, the entire apparatus was mounted to a rocking frame which can operate in the horizontal or vertical position. The apparatus was tested by measuring the solubility of NaCl in water at temperatures between 345 and 516 K at saturation pressure. Results are in good agreement with existing literature values. DOE

STUDIES OF SELENIUM AND XENON IN INDUCTIVELY COUPLED PLASMA MASS SPECTROMETRY Ph.D. Thesis

T. Bricker 27 Jul. 1994 65 p
(Contract W-7405-eng-82)
(DE95-001676; IS-T-1701) Avail: CASI HC A04/MF A01

Since its development, inductively coupled plasma mass spectrometry (ICP-MS) has been a widely used analytical technique. ICP-MS offers low detection limits, easy determination of isotope ratios, and simple mass spectra from analyte elements. ICP-MS has been successfully employed for many applications including geological, environmental, biological, metallurgical, food, medical, and industrial. One specific application important to many areas of study involves elemental speciation by using ICP-MS as an element specific detector interfaced to liquid chromatography. Elemental speciation information is important and cannot be obtained by atomic spectrometric methods alone which measure only the total concentration of the element present. Part 1 of this study describes the speciation of selenium in human serum by size exclusion chromatography (SEC) and detection by ICP-MS. Although ICP-MS has been widely used, room for improvement still exists. Difficulties in ICP-MS include noise in the background, matrix effects, clogging of the sampling orifice with deposited solids, and spectral interference caused by polyatomic ions. Previous work has shown that the addition of xenon into the central channel of the ICP decreases polyatomic ion levels. In Part 2 of this work, a fundamental study involving the measurement of the excitation temperature is carried out to further understand xenon's role in the reduction of polyatomic ions. DOE

STRONG INTERACTIONS STUDIES WITH MEDIUM ENERGY PROBES

K. K. Seth Sep. 1994 19 p
(Contract DE-FG02-87ER-40344)
(DE95-001800; DOE/ER-40344/8) Avail: CASI HC A03/MF A01

This progress report refers to the period August 1993 to September 1994, which includes the second year of the three year period December 1, 1992 - November 30, 1995 of our existing research contract. The budget proposal for the third year, December 1, 1994 to November 30, 1995 as originally approved, is also presented. As anticipated in our 1992 - 1995 proposal, Fermilab E760/E835 on high precision charmonium spectroscopy has remained a major part of our preoccupation and commitment during the last year, and it will remain so in the forthcoming year. In early 1994 we joined the collaboration of the Brookhaven experiment E852 on the spectroscopy of states with exotic quantum numbers. The first successful three month run of E852 was completed on July 31 and preliminary data analysis has been started. Some new commitments have resulted from this collaboration and a separate proposal for supplemental financial support is being prepared for them. At Los Alamos our experiment (number sign)1274 on search of extremely neutron rich exotic nuclei by pion absorption began making initial measurements a month ago and is expected to take data during the period October 15 - November 30, 1994. In addition to the above on-going programs, our Bates proposal (94-01) for a definitive measurement of the quenching of the longitudinal response in quasi-free scattering of electrons from nuclei has been approved with high priority for 600 hours of beam time, and we expect to start the experiment in late 1995. DOE

SURFACE SECOND HARMONIC STUDIES OF SI(111)/ELECTROLYTE AND SI(111)/SIO2/ELECTROLYTE INTERFACES Technical Report, Jun. 1993 - May 1994

P. R. Fischer, J. L. Daschbach, and G. L. Richmond 13 May 1994 17 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-89-J-1261)
(AD-A279450; TR-9) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The optical second harmonic (SH) response from Si(111) electrode surfaces has been studied and has been found to be highly potential dependent. For both H-terminated Si(111) surfaces in NH4F, and oxide covered surfaces biased in H2SO4, the phase and the amplitude display a potential dependence which we attribute to field effect within the semiconductor space-charge region and at the surface of the Si(111) electrode. The studies are the first to demonstrate that for Si(1110)/oxide samples the potential dependence in the SH phase can be correlated with oxide thickness as demonstrated by examining samples of 0-40 Angstrom thickness. Total internal reflection second harmonic generation (TIRSHG) has made possible the study of a series of neat n-alkane/water interfaces. Analysis of the incident and polarization angular dependent SH response allows for determination of interfacial nonlinear molecular properties. The measured surface nonlinear susceptibilities may be indicative of a high degree of interfacial order. DTIC

TIME OF FLIGHT SPECTROSCOPY WITH MUONIC HYDROGEN

G. M. Marshall, J. M. Bailey (Liverpool Univ., England.), G. A. Beer (Victoria Univ., British Columbia.), J. L. Beveridge, J. H. Brewer (British Columbia Univ., Vancouver, British Columbia.), M. Fujiwara (British Columbia Univ., Vancouver, British Columbia.), T. M. Huber (Gustavus Adolphus Coll., Saint Peter, MN.), R. Jacot-Guillarmod (Fribourg Univ., Switzerland.), P. Kammel (Academy of Sciences, Vienna, Austria.), and P. E. Knowles (Victoria Univ., British Columbia.) et al 1993 4 p Presented at the International Workshop on Low Energy Muon Science, Santa Fe, NM, 4-8 Apr. 1993 Sponsored in cooperation with NSERC, NATO, and Research Corp.
(Contract DE-FG02-87ER-40333)
(DE94-017056; DOE/ER-40333/142; COO-2197-142; CONF-9304145-4)
Avail: CASI HC A01/MF A01

Time of flight techniques coupled with muonic deuterium and tritium atoms in vacuum can be used to measure parameters important in the understanding of muon catalyzed fusion interactions. Muonic deuterium atomic beams with energy of order 1 eV have been produced via transfer and emission from solid hydrogen containing small deuterium concentrations. Measurements of energy loss in pure deuterium are presented which test calculations of sigma(sub (mu)d+D). Muonic tritium beams should be produced in a similar way, with an energy distribution which overlaps the predicted muonic molecular (d(mu)t) formation resonances. The existence of resonances is crucial for high cycling rates in muon catalyzed fusion, but direct experimental verification of strengths and energies is not yet possible by other means. Results of simulations demonstrate how the resonance structure might be confirmed. DOE

PREPARATION AND X-RAY STRUCTURE OF Cp2Ti(PH2SiH2)(PMe3)

Esther Spaltenstein, Pilar Palma, Kristina A. Kreutzer, Christopher A. Willoughby, and William M. Davis 18 Oct. 1994 11 p
(Contract N00014-91-J-1043)
(AD-A286197; TR-7) Avail: CASI HC A03/MF A01

The synthesis and x-ray structure determination of the novel complex, Cp2Ti(Ph2SiH2)(PMe3), (4), is reported. The spectroscopic and structural data indicate that (4) is best described as being a hybrid between a titanium(4)(silyl)hydride complex and a titanium(2) silane complex. Complex (4) reacts reversibly with N2 to form the bridging dinitrogen complex (5) and, in the presence of norbornene, (4) catalytically dimerizes Ph2SiH2 in quantitative yield. DTIC

APPLICATIONS OF ICP MAGNETIC SECTOR MULTICOLLECTOR MASS SPECTROMETRY TO BASIC ENERGY RESEARCH Progress Report, 1 Dec. 1993 - 31 Aug. 1994

A. N. Halliday and C. M. Hall Sep. 1994 14 p
(Contract DE-FG02-94ER-14412)
(DE95-002600; DOE/ER-14412/1) Avail: CASI HC A03/MF A01

The prototype Inductively-Coupled Plasma (ICP) magnetic sector multicollector mass spectrometer has been installed and commissioned at the University of Michigan. Following performance evaluation and instrument characterization, the absolute abundances of isotopes of tin have been measured with precisions unproved by up to an order of magnitude over those of currently accepted, values. An efficient chemical separation technique for In and Sn in Zn, Cu and Fe sulfides and in silicate matrices has been successfully developed. The predicted Sn-115 anomaly that results from the decay of In-115, has been measured in sulfides. Precise isotopic measurements of molybdenum, tellurium, hafnium, tungsten and platinum have been made. A new ND-YAG laser ablation microsampling device on line to the mass spectrometer for in situ isotopic analysis at high precision has been commissioned and tested with accurate measurements of Sr, W and Pb on standard silicate materials. Studies in an ambient temperature chloroaluminate molten salt composed of aluminum chloride and 1-ethyl-3-methylimidazolium chloride were carried out. A variety of topics were investigated. Work on poly(p-phenylene) and silane based electroactive polymers was carried out. The electrochemistry of several Ru and Co complexes was examined, as was the kinetics of the ferroceneferrocenium couple as a function of melt viscosity. The electrochemistry of anthracene and 9,10 anthraquinone was examined under conditions where protonation of these species was important. Finally, proton speciation and proton equilibrium were examined by NMR and FT-IR spectroscopies. DTIC

BRIDGING THE PRESSURE GAP: IN SITU ATOMIC-LEVEL INVESTIGATIONS OF MODEL PLATINUM CATALYST SURFACES UNDER REACTION CONDITIONS BY SCANNING TUNNELING MICROSCOPY Ph.D. Thesis

Brian James McIntyre May 1994 229 p
(Contract DE-AC03-76SF-00098)
(DE95-002346; LBL-36065) Avail: CASI HC A11/MF A03

Results of this thesis show that STM measurements can provide information about the surfaces and their adsorbates. Stability of Pt(110) under high pressures of H2, O2, and CO was studied (Chap. 4). In situ UHV and high vacuum experiments were carried out for sulfur on Pt(111) (Chap.5). STM studies of CO/S/Pt(111) in high CO pressures showed that the Pt substrate undergoes a stacking-fault-domain reconstruction involving periodic transitions from fcc to hcp stacking of top-layer atoms (Chap.6). In Chap.7, the stability of propylene on Pt(111) and the decomposition products were studied in situ with the HPSTM. Finally, in Chap.8, results are presented which show how the Pt tip of the HPSTM was used to locally rehydrogenate and oxidize carbonaceous clusters deposited on the Pt(111) surface; the Pt tip acted as a catalyst after activation by short voltage pulses. NON-LOCAL DENSITY FUNCTIONAL CALCULATIONS OF GAS PHASE HEATS OF FORMATION

Dariush Habibollahzadeh, M. E. Grice, Monica G. Concha, Jane S. Murray, and Peter Politzer 3 Nov. 1994 11 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-91-J-4057)
(AD-A286213) Avail: CASI HC A03

A general procedure is presented for computing the gas phase heats of formation of a wide variety of organic compounds. Delta E for the formation of the molecule from its elements at 0 K is obtained from density functional calculations (Gaussian 92/DFT) for optimized geometries. This result is converted to Delta H at 298 K by assuming ideal behavior and adding the translational, rotational, and vibrational energies. Additive correction terms corresponding to the various coordination states of the carbons, nitrogens, and oxygens were developed using a data base of 54 compounds. The experimental Delta H deg sub f values of these compounds are then reproduced with an average absolute error of 3 kcal/mole and a standard deviation of 4 kcal/mole. For a group of ten test cases that were not part of the data base, the average absolute error is 3.5 kcal/mole and the standard deviation is 4.1 kcal/mole. DTIC

THE APPLICATION OF ELECTRODIALYSIS TO EXTEND THE LIFETIME OF COMMERCIAL ELECTROPLATING BATHS

G. Purdy, C. Zawodzinski, B. Smith, and W. H. Smith 1993 13 p
Presented at the 8th Symposium on Separation Science and Technology for Energy Applications, Gatlinburg, TN, 24-28 Oct. 1993
(Contract W-7405-eng-36)
(DE95-000868; LA-UR-94-3090; CONF-9310360-1) Avail: CASI HC A03/MF A01

Electrodialysis has been investigated as a method to extend the lifetime of industrial electroplating solutions via the selective removal of inert electrolyte salts that build up during electroplating operations. The electrodialysis measurements were made using a commercially available plate-and frame-type cell and various combinations of Nafion cation change and either Tosflex or Neosepta anion exchange membranes. Two commercial plating solutions were studied: a zinc-tin bath in which there is a buildup of excess potassium hydroxide and a nickel-tungsten bath characterized by a buildup of excess sodium sulfate. Potassium hydroxide was effectively removed from the zinc-tin bath with very little loss of the heavy metals. Two configurations were investigated: a three compartment configuration with potassium hydroxide in the anolyte strip and sulfuric acid in the catholyte strip, and a two compartment configuration with sulfuric acid in the catholyte strip and the anode placed directly in the plating solution. In both cases potassium hydroxide was stripped from the plating solution at greater than 94% current efficiency, but at a slightly greater voltage in the three compartment cell due to increased resistance caused by the extra membrane. A three compartment configuration was used to remove sodium sulfate from the nickel-tungsten bath, with acid solution in the catholyte and alkaline solution in the anolyte. Current efficiencies for salt removal were high but with appreciable loss of tungsten and nickel to the strip solutions. DOE

CATALYZED REDUCTION OF NITRATE IN AQUEOUS SOLUTIONS
P. A. Haas Aug. 1994 17 p
(Contract DE-AC05-84OR-21400)
(DE94-017660; ORNL/TM-12800) Avail: CASI HC A03/MF A01

Sodium nitrate and other nitrate salts in wastes is a major source of difficulty for permanent disposal. Reduction of nitrate using aluminum metal has been demonstrated, but NH3, hydrazine, or organic compounds containing oxygen would be advantageous for reduction of nitrate in sodium nitrate solutions. The objective of this seed money study was to determine minimum conditions for reduction. Proposed procedure was batch heating of aqueous solutions in closed vessels with monitoring of temperatures and pressures. A simple, convenient apparatus and procedure were demonstrated for observing formation of gaseous products and collecting samples for analyses. The test conditions were 250 C and approximately 1000 psi max. Any useful reduction of sodium nitrate to sodium hydroxide as the primary product was not found. The nitrate present at pHs less than 4 as HNO3 or NH4NO3 is easily decomposed, and the effect of nitromethane at these low pHs was confirmed. When acetic acid or formic acid was added, 21 to 56% of the nitrate in sodium nitrate solutions was reduced by methanol or formaldehyde. With hydrazine and acetic acid, 73 % of the nitrate was decomposed to convert NaNO3 to sodium acetate. With hydrazine and formic acid, 36% of the nitrate was decomposed. If these products are more acceptable for final disposal than sodium nitrate, the reagents are cheap and the conversion conditions would be practical for easy use. Ammonium acetate or formate salts did not significantly reduce nitrate in sodium nitrate solutions. DOE

An evaluated mechanism of elementary rate constants and thermodynamics for methane combustion was developed. The experimental data set and sensitivity computations for the optimization procedure were selected and completed; the optimization calculations were begun. Important kinetics measurements and analysis were made to aid in this endeavor. Shock tube experiments determined CH3 and OH concentrations in CH4-O2-Ar mixtures for the optimization. Quantum calculations were performed for the CH + N2 reaction. Modeling studies examined the development of reduced and skeletal mechanisms and the prediction of NO and soot levels in diesel engines. AB INITIO POTENTIAL ENERGY SURFACE FOR H + OCS REACTIONS: EXTENDED BASIS SETS AND CORRELATION TREATMENT Final Report, Sep. 1993 - Jun. 1994
Betsy M. Price and Cary F. Chabalowski Nov. 1994 35 p
(DA Proj. 1L1-61102-AH-43)
(AD-A286420; ARL-TR-629) Avail: CASI HC A03/MF A01

Ab initio calculations using extended basis sets are presented for the potential energy surface (PES) of H + OCS. There are two major reaction channels on the PES; Reaction (1) is H(2S) + OCS(1(Sigma)) yields OH(2(Pi)) + CS(1(Sigma)), and Reaction (2) is H(2S) + OCS(1(Sigma)) yields SH(2(Pi)) + CO(1(Sigma)). Results of this study substantiate findings from an earlier quantum chemical study using a lower level of theory, including (1) the existence of 12 transition states and 6 stable 4-body intermediates; (2) the qualitative description of the PES (i.e., geometries, relative barriers, and well depths are similar to those in the earlier study); and (3) the entrance channel transition states leading to (2) are tight, as suggested by experiment. The results presented here also support the explanations of observed product energy distributions for (1) and (2) based on the earlier ab initio study. An additional transition state connecting the cis-HOCS and cis-HSCO minima was located, confirming a previous suggestion that Reaction (2) could result from hydrogen migration after HOCS formation. The current results show a substantial improvement in the quantitative agreement with experiment over the previously calculated values. DTIC

Chester (Mobil Research and Development Corp., Paulsboro, NJ.) 1994 7 p Presented at the Fall Meeting of the Materials Research Society, Boston, MA, 28 Nov. - 2 Dec. 1994 Prepared in cooperation with BNL, Upton, NY
(Contracts DE-AC04-94AL-85000; DE-AC02-76CH-00016)
(DE95-003355; SAND-94-2716C; CONF-941115-1) Avail: CASI HC A02/MF A01

Hydroxylated alumina films have been synthesized by water oxidation of single crystal Al(110) surfaces. Thermal dehydroxylation results in anion vacancies which produce an Al(3s) defect state 3.5 eV below the conduction band edge. A maximum in the defect-DOS occurs for oxides heated to 350 to 400C, which is where the materials exhibit maximum Lewis acidity with respect to C2H4. Adsorbed C2H4 produces thermally active C2 species which interact covalently with the defect-DOS and nonbonding O(2p) from the top of the valence band. C(1s) binding energies suggest significant charge transfer which is consistent with a carbenium ion. Ni evaporated onto the surface, however, transfers charge directly to Al species and does not interact with O atoms at the defect site. The defect-DOS is regenerated when the C2 species decomposes or when Ni migrates thermally through the oxide layer. DOE

THE THERMAL CONDUCTIVITY OF SILICON NITRIDE WITH MOLYBDENUM DISILICIDE ADDITIONS
S. C. Beecher, R. B. Dinwiddie, A. M. Abeel, and R. A. Lowden 1993

10 p Presented at the 22nd International Thermal Conductivity Conference, Tempe, AZ, 7-10 Nov. 1993
(Contract DE-AC05-84OR-21400)
(DE94-017757; CONF-9311131-5) Avail: CASI HC A02/MF A01

Room-temperature thermal conductivity has been measured for a series of silicon nitride (Si3N4) matrix composites with molybdenum disilicide (MoSi2) additions of 2, 5, 10, 25 and 50 wt. %. Included in these measurements were a pure MoSi2 sample and a Si3N4 sample containing only sintering aids. Aluminum oxide (Al2O3) and yttrium oxide (Y2O3) were added as the sintering aids, at approximately 6 and 2 respectively. When the amount of MoSi2 was increased to greater than 10 wt. %, the amount of the sintering aids necessary to densify the composite was decreased. No sintering aids were added to the pure MoSi2 sample. Thermal conductivities of the Si3N4 sample without MoSi2 and the pure MoSi2 sample wee 36 W/m.K and 52 W/m.K respectively, which agree very well with the literature values for similar materials. No statistically significant changes were observed in the thermal conductivity for those samples containing up to 10 wt. % MoSi2. However, between 10 and 25 wt. % MoSi2 there was a dramatic decrease in the thermal conductivity from 37 to 20.9 W/m.K. The thermal conductivity then increased steadily with further additions of MoSi2 up to 52 W/m.K for the pure MoSi2 specimen. DOE

THE MODIFIED EMBEDDED ATOM METHOD
M. I. Baskes Aug. 1994 27 p
(Contract DE-AC04-94AL-85000)
(DE94-017958; SAND-94-8704) Avail: CASI HC A03/MF A01

Recent modifications have been made to generalize the Embedded Atom Method (EAM) to describe bonding in diverse materials. By including angular dependence of the electron density in an empirical way, the Modified Embedded Atom Method (MEAM) has been able to reproduce the basic energetic and structural properties of 45 elements. This method is ideally suited for examining the interfacial behavior of dissimilar materials. This paper explains in detail the derivation of the method, shows how the parameters of the MEAM are determined directly from experiment or first principles calculations, and examines the quality of the reproduction of the database. Materials with fcc, bcc, hcp, and diamond cubic crystal structure are discussed. A few simple examples of the application of the MEAM to surfaces and interfaces are presented. Calculations of pullout of a SiC fiber in a diamond matrix as a function of applied stress show non-uniform deformation of the fiber. DOE

QUANTUM CHEMICAL STUDY OF RARE GAS/HALIDE INTERACTIONS AS A MODEL FOR HIGH ENERGY DENSITY MATERIAL. 2: THE INTERACTION OF HYDROGEN CHLORIDE WITH THE RARE GAS XENON Final Report, Sep. 1989 - Sep. 1991
George F. Adams and Cary F. Chabalowski Nov. 1994 41 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DA Proj. 1L1-61102-AH-43)
(AD-A286385; ARL-TR-621) Avail: CASI HC A03

Electronic transitions from laser excitation have produced charge transfer (CT) reactions in doped xenon solids, which in turn generate spatially separated, long-lived, dipolaron states. These quasi-stable separated charges have been as an energy storage mechanism in the study of high-energy density materials. In a previous study, we performed calculations on selected singlet electronic state of HCl, and in this study we investigate the character of the low-lying singlet electronic states in the systems Cl + Xe and HCl + Xe. The results show at least one excited electronic state which is ionic in nature and could serve as a CT state. It is also known from experimentation that following excitation into the CT state, the H-Cl bond is ruptured. The CT state located in this study is described primarily by a molecular orbital with sigma-antibonding character in the H-Cl bonding region. This CT state would therefore provide both a charge transfer mechanism and a means for weakening or breaking the H-Cl bond consistent with experimental observations. In this report, we also provide potential energy surfaces and electronic transition probabilities as a function of R(HC1...Xe) for a linear arrangement. DTIC

CATALYTIC REACTIONS OF SYNTHESIS GAS. PART 3. DETERMINATION OF REACTION KINETICS
M. Niemelae 1993 44 p See also PB93-179448
(PB95-127759; ISBN-951-22-1902-6) Avail: CASI HC A03/MF A01

The review is aimed at introducing the basic concepts of experimental kinetic procedures relevant in the present characterization and testing of heterogeneous transition metal catalysts in a fixed bed tubular reactor, Carberry spinning basket gradientless reactor, or a batch screening reactor in synthesis gas or methanol homologation reaction. The term differential reactor means a reactor in which the conversion is limited to not more than a few percent. Under these conditions the rate can be calculated directly at fixed concentrations. The obtained rate data may be fit to a reaction rate law, which could provide information on the reaction mechanisms, in order to determine the values of reaction rate constant, activation energy, and individual reaction orders. SEPARATION OF PROTEINS BY CONVECTIVE ELECTROPHORESIS THROUGH A POROUS MEMBRANE Ph.D. Thesis
M. Vuoristo 20 Jun. 1994 39 p
(PB95-127130) Avail: CASI HC A03/MF A01

The development of a continuous convective electrophoresis (CCE) method for separation of proteins is presented. The separation in the porous membrane has been modelled by solving the extended Nernst-Planck equations for protein transport. The separation efficiency has been demonstrated by simulations and by experiments with four different mixtures of model proteins: Cytochrome c - Bovine Serum Albumin, Cytochrome c - Lysozyme, Human Serum Albumin - Haemoglobin and pyrogen contaminated Human Serum Albumin. The results of the separation experiments were in good agreement with the predictions of the mathematical model. Relatively high separation efficiency were obtained with all protein pairs studied in a continuous one-step process. NTIS

SYNTHESIS AND CHARACTERIZATION OF SINGLE-SOURCE MOLECULAR PRECURSORS TO BINARY METAL SULPHIDES: BIS(DIETHYLDITHIOCARBAMATO) M(2)TRIALKYLPHOSPHINE (M = Zn AND Cd) ADDUCTS
D. Zeng, M. Hampden-Smith, and T. M. Alam 6 May 1994 41 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-91-J-1258)
(AD-A279746) Avail: CASI HC A03

Monomeric, five-coordinate bis(diethyldithiocarbamato)M(2)-(trialkylphosphine) complexes, 1 (M=Zn, a lkyl=Me), 2 (M=Zn, alkyl=Et), 3 (M=Cd, alkyl=Me), and 4 (M=Cd, alkyl=Et) have been synthesized by addition of trialkylphosphine ligands to toluene solutions of bis(diethyldithiocarbamato)M(II) (M=Zn, and Cd). The bidentate ligand, 1,2-bis(diethylphosphino)ethane (DEPE) reacted with bis(diethyldithiocarbamato)M(II) (M=Zn, Cd) and a 1:1 mixture of (Et2NCS2)2Zn2:(Et2NCS2)2Cd2 in toluene to form five-coordinate, dinuclear DEPE-bridged complexes, (Et2NCS2)2M2(mu-DEPE), 5 (M=Zn), 6 (M=Cd) and 7 (Et2NCS2)2Zn(muEt2PCH2CH2PEt2)Cd(Et2NCS2)2, respectively. The composition and structure of all compounds was confirmed by elemental analyses, infra-red spectroscopy, 1H, 13C (1H) and 31P(1H) nuclear magnetic resonance (NMR) and in selected cases by X-ray crystallography. The solid-state structures of (Et2NCS2)2ZnPMe3(1) and (Et2NCS2)2CdPEt3(4) have been determined by single-crystal X ray diffraction. Thermogravimetric analysis (TGA) of compounds 1-3 showed that the PR3 ligands dissociated prior to thermal decomposition. However, compound 4 exhibited a single weight loss to give crystalline CdS as determined by X ray powder diffraction, electron diffraction and transmission electron microscopy. The homobimetallic species, 5 and 6 also decomposed to give ZnS and CdS, respectively while the heterobimetallic species, 7, thermally decomposed to give crystalline Zn0.5S according to X ray powder diffraction data. We discuss similarities and differences between spatially localized solutions of the quintic complex Ginzburg-Landau equation applicable near a weakly inverted bifurcation to traveling waves and localized states observed during the catalytic oxidation of CO on Pt(110). It turns out that both, the properties of a single localized state as well as their interaction, share many common features in comparing the two systems. We point out that the experimental results rule out a solitonic mechanism and are only compatible with the picture of a dissipative driven system. DOE

MIXED-SPUTTER DEPOSITION OF Ni-Ti-Cu SHAPE MEMORY FILMS
P. Krulevitch, P. B. Ramsey, D. M. Makowiecki, A. P. Lee, M. A. Northrup, and G. C. Johnson (California Univ., Berkeley, CA.) May 1994 16 p
(Contract W-7405-eng-48)
(DE94-017296; UCRL-ID-115719) Avail: CASI HC A03/MF A01

Ni-Ti-Cu shape memory films were mixed-sputter deposited from separate nickel, titanium, and copper targets, providing increased compositional flexibility. Shape memory characteristics, examined for films with 7 at.% Cu and 41-51 at.% Ti, were determined with temperature controlled substrate curvature measurements, and microstructure was studied with transmission electron microscopy. The Ni-Ti-Cu films were found to have shape memory properties comparable to bulk materials, with transformation temperatures between 20 and 62 C, a 10-13 C hysteresis, and up to 330 MPa recoverable stress. A REVIEW OF MICROBIALLY INDUCED CORROSION (MIC) OF STEEL AND A PRELIMINARY INVESTIGATION TO DETERMINE ITS OCCURRENCE IN NAVAL VESSELS
John F. Upsher May 1993 25 p Original contains color illustrations
(MRL-GD-0048; AR-008-241) Copyright Avail: Issuing Activity

A study was made of the mechanisms of microbially induced corrosion of steels and of influencing factors. The main causative organisms were the sulfate reducing bacteria (SRB) which require little more than a wet situation with depleted oxygen, some small organic molecules and sulfate. The corrosive effect is primarily by cathodic depolarization but local abundance of sulfide and pH change are also involved. SRB were detected at one third of the corrosion sites examined on three Naval ships. They were also present in their oily water wastes which would be a source of infection of any exposed steel surfaces. Based on current information, no special measures to counter microbially induced corrosion of ship steel are recommended but antibacterial treatments warrant further investigation as remedial measures for active microbially induced corrosion (MIC) areas. The corrosion resistance of many metals and alloys depend on their ability to repassivate after breakdown of the passive film. Following breakdown localized corrosion takes place. The consequences of initiation events depends on many factors leading to a dissolution rate of the metal which may be continuous, intermittent or transitory. Major changes in the solution chemistry at the breakdown site must take place to enable active dissolution to take place and prevent repassivation. However, mass transfer of the dissolution products to the bulk environment often plays a decisive role. The composition of the environment is important. Some species inhibit while others stimulate the anodic dissolution. In the presence of particular cations, deposition slowly takes place on cathodic sites. Current density mapping measurements have been used to study pitting processes on iron and aluminum alloys. The effects of phosphate as an anodic inhibitor for steel and cerium as a cathodic inhibitor for aluminum are discussed in conjunction with related chemical processes. DOE

PROCESSING AND CHARACTERIZATION OF Ni-Al-Fe-B SHAPE-MEMORY ALLOY WIRES PRODUCED BY RAPID SOLIDIFICATION
D. S. Easton, C. T. Liu, J. A. Horton, E. P. George, and J. J. Campbell 1993 4 p Presented at the International Union of Materials Research Societies on Advanced Materials, Tokyo, Japan, 31 Aug. - 4 Sep. 1993
(Contract DE-AC05-84OR-21400)
(DE94-017702; CONF-9308122-19) Avail: CASI HC A01/MF A01

This work describes net-shape ductile wires of Ni-Al-Fe doped with boron produced directly from the melt by in-rotating-liquid (IRL) melt spinning, thus avoiding the difficult and costly problem of fabricating bulk castings. This method produces wires of 0.1 to 0.5 mm dia and lengths to 2 m. X ray diffraction scans showed that the as-spun wires consist of B2, Ll2, and bct martensite phases and that the B2 phase further transforms to bct martensite upon cold working. Shape-memory behavior showed an Ap temperature of (approximately) 180 C as measured by bend recovery tests and by tensile cycling tests. Effects on the wires of IRL processing parameters are discussed. DOE

Cr2Nb DEVELOPMENT
C. T. Liu, J. A. Horton, and C. A. Carmichael 1994 12 p Presented at the 7th Annual Conference on Fossil Energy Materials, Oak Ridge, TN, 11-13 May 1993
(Contract DE-AC05-84OR-21400)
(DE94-018697; CONF-9305135-10) Avail: CASI HC A03/MF A01

Microstructure and mechanical properties of Cr-Nb alloys containing 5.6 to 17% Nb were studied for high-temperature structural applications. The alloys basically contain the two phases of Cr2Nb and chromium-rich solid solution. Re, Al, Ni, Fe and Co were added to the alloys for control of microstructure and properties. The alloys show excellent strength at temperatures to 1250 C. Among the alloying elements, rhenium is found to be most effective in improving the mechanical properties at room and elevated temperatures. Alloying with greater than or equal to 8% Al, Ni, and Co, on the other hand, lowers the strength and ductility at elevated temperatures. Further development is required to improve the fracture resistance of the alloys at ambient temperatures. DOE

FABRICATION AND PROPERTIES OF ALUMINA MATRIX COMPOSITES CONTAINING NICKEL ALUMINIDE REINFORCEMENTS
K. B. Alexander, H. T. Lin, J. H. Schneibel, and P. F. Becher 1994 6 p Presented at the Fall Meeting of the Minerals, Metals and Materials Society: Physical Metallurgy and Materials, Pittsburgh, PA, 17-21 Oct. 1993
(Contract DE-AC05-84OR-21400)
(DE94-018703; CONF-931009-30) Avail: CASI HC A02/MF A01

Ductile nickel-aluminide intermetallic alloys have been successfully used to toughen ceramic materials intended for use at a wide range of temperatures. Traditional ceramic processing procedures have been used to produce a variety of microstructures. The fracture toughness increases with increasing particle aspect ratio, however, the flexural strength decreases with increasing particle size. Fracture toughnesses up to 7.6 MPa m(sup 1/2) and flexural strengths up to 550 MPa were observed in an alumina composite containing 10 vol.% nickel aluminide. DOE

MECHANICAL BEHAVIOR OF 97.2% W ALLOY IN TENSION AT HIGH TEMPERATURES Final Report
John L. Green Sep. 1994 22 p
(AD-A284797; ARL-TR-508) Avail: CASI HC A03/MF A01

The objective was to investigate the behavior of 97.2% tungsten alloy in tension. A modified button head specimen was heated using resistive heating techniques. The affect high temperatures, medium strain rates, and heating rates had on the stress-strain results were observed. A high speed optical pyrometer and an optical clip gage were utilized for temperature and strain measurements. The optical clip gage could measure strain at strain rates up to 11.8/s. The room temperature experiments were at strain rates of 10-(exp 4)/s, 10-(exp 2)/s, and 5/s. The high heating rate experiments were at temperatures of 727 C, and 1097 C, heating rates of 5.4 C/sec and 536 C/sec and a strain rate of 5/s. Increase in yield point and flow stress were observed as the heating rate was increased. A modified Johnson-Cook (MJ+C) material model was proposed to include the effect of heating rate. The constants in the MJ+C model were determined based on the experimental results. DTIC

FRACTURE TOUGHNESS PROPERTIES OF WELDED STAINLESS STEELS FOR TRITIUM SERVICE
M. Morgan 1994 5 p Presented at the 19th Department of Energy Conference on Compatibility, Aging and Service Life, Los Alamos, NM, 28-30 Sep. 1994
(Contract DE-AC09-89SR-18035)
(DE95-000755; SRTC-MTS-94-3017; CONF-9409181-6) Avail: CASI HC A01/MF A01

Studies to determine tritium exposure effects on the properties of welded steels are being conducted. In this investigation, the effects of tritium and decay helium on the fracture toughness properties of high-energy-rate-forged (HERF) Incoloy 903 were measured. Fracture toughness measurements were conducted for tritium-exposed samples in the as-forged condition and compared with welded samples. Tritium-exposed HERF Incoloy 903 had fracture toughness values that were 33% lower than those for unexposed HERF Incoloy 903. Tritium-exposed welded samples had fracture toughness values that were just 8% of the unexposed HERF alloys and 28% of unexposed welded alloys. DOE

N95-20088# Pacific Northwest Lab., Richland, WA.
POST-IRRADIATION DEFORMATION CHARACTERISTICS OF HEAVY-ION IRRADIATED 304L SS
J. I. Cole (Washington State Univ., Pullman, WA.) and S. M. Bruemmer Jun. 1994 12 p Presented at the 17th Symposium on Effects of Radiation on Materials, Sun Valley, ID, 20-23 Jun. 1994
(Contracts DE-AC06-76RL-01830; DE-FG06-89ER-75522)
(DE94-017462; PNL-SA-23641; CONF-940657-5) Avail: CASI HC A03/MF A01

Post-irradiation deformation behavior in Ni-ion-irradiated 304L stainless steel (SS) is examined as a function of radiation dose and deformation temperature. For similar strain levels, specimens exhibit a transition from dislocation slip to deformation-induced twinning at 25 C with increasing radiation dose. At 288 C twinning is no longer observed and highly localized slip occurs by the formation of narrow 'channels' containing a reduced defect density. The observations are discussed in terms of radiation-induced defect character and expected deformation mechanisms. DOE

DEVELOPMENT OF SUPERPLASTICITY IN 5083 ALUMINUM WITH ADDITIONS OF Mn AND Zr
C. A. Lavender, J. S. Vetrano, M. T. Smith, S. M. Bruemmer, and C. H. Hamilton (Washington State Univ., Pullman, WA.) May 1994 8 p Presented at the International Conference on Superplasticity in Advanced Materials (ICSAM), Moscow, Russia, 24-26 May 1994
(Contract DE-AC06-76RL-01830)
(DE94-017474; PNL-SA-23032; CONF-9405193-3) Avail: CASI HC A02/MF A01

The superplastic behavior of the 5083 aluminum alloy with additions of Mn and Zr was studied by uniaxial tensile testing and microstructural evaluations. Additions of up to 0.2% Zr and 0.8% Mn were made to a base 5083 aluminum alloy to decrease the grain size and improve superplastic behavior. Constant strain-rate tensile test data were used to determine strain-rate sensitivity (m values) and elongations-to-failure for the alloys at strain rates ranging from 4 x 10(exp -4) to 1 x 10(exp -1) s(exp -1) at temperatures of 450 to 550 C. Elongations-to-failure of up to 400% at 1 x 10(exp -2) s(exp -1) were achieved for the modified alloys. The strain-rate sensitivity for the alloys as a function of strain was determined and two distinct behaviors were observed. For the alloys having composition close to the base 5083 alloy, the m value steadily decreased with increasing strain; however, in alloys with higher levels of Zr, the m value remained stable. A maximum m value of 0.65 was achieved at 0.7 strain for the 1.6% Mn and 0.2% Zr alloy at 1 x 10(exp -3) s(exp -1). DOE

N95-20122# Lawrence Livermore National Lab., Livermore, CA.
DUCTILE-BRITTLE TRANSITION BEHAVIOR OF TUNGSTEN UNDER SHOCK LOADING
D. H. Lassila and G. T. Gray, III (Los Alamos National Lab., NM.) Feb. 1994 8 p Presented at the EURODYMAT 1994: 1st International Conference on Mechanical and Physical Behavior of Materials Under Dynamic Loading, Oxford, England, 26-30 Sep. 1994
(Contract W-7405-eng-48)
(DE94-009913; UCRL-JC-116339; CONF-940956-7) Avail: CASI HC A02/MF A01

The ductile-brittle transition behavior of warm-forged tungsten under shock loading conditions was examined by performing shock/soft-recovery experiments at 22 C and 400 C. The results of a recovery experiment at 22 C indicate that shock (19 GPa)-induced strains were accommodated by fracture processes, i.e. there were no indications of shock-induced plastic deformation, and the test sample was reduced to rubble. At 400 C the test sample was recovered intact and the shock-induced plasticity caused deformation banding and an increase in the dislocation density of the material. The results of these experiments demonstrate the principle of a ductile-brittle transition behavior of tungsten under uniaxial shock loading conditions and indicate that explosively driven deformation of the material studied will likely result in pulverization due to shock loading. DOE

MAGNETICALLY CONTROLLED DEPOSITION OF METALS USING GAS PLASMA
D. M. Woodall and E. C. Lemmon Jul. 1994 27 p
(Contract DE-FG07-93ID-13220)
(DE94-018654; DOE/ID-13220/T1) Avail: CASI HC A03/MF A01

Thin layers of secondary material are plated on substrates either by plating or spraying processes. Plating operations produce large amounts of hazardous liquid wastes. Spraying, while one of the less waste intensive methods, produces 'over spray' which is waste that is a result of the uncontrolled nature of the spray stream. In many cases the over spray produces a hazardous waste. Spray coating is a mature process with many uses. Material can be deposited utilizing spraying technology in three basic ways: 'flame spraying,' direct spraying of molten metals, and/or plasma spraying. This project is directed at controlling the plasma spraying process and thereby minimizing the waste generated in that process. Examples of spraying applications that may benefit substantially from this technology are: (1) preparing printed circuit boards and (2) tinning circuit boards with lead in preparation for soldering components. There are many applications of spraying technology that can benefit from a controlled spraying scheme. They include: (1) titanium coating on bio-implants, (2) wear-tolerant ceramic thermal barriers using partially stabilized zirconia (PSZ), (3) alumina and alumina-titania wear resistant-coatings, and (4) ceramic superconductor manufacture using hollow spherical powders. DOE

ENHANCEMENT OF CORROSION RESISTANCE AND MECHANICAL PROPERTIES OF LIGHT-WEIGHT METALS THROUGH THE USE OF GRADED NONEQUILIBRIUM MICROSTRUCTURES Technical Report, 1 Jul. 1993 - 30 Jun. 1994

B. A. Shaw and K. A. Kennedy Oct. 1994 65 p
(Contract N00014-93-1-0537)
(AD-A286320) Avail: CASI HC A04/MF A01

Designs for the future will place extreme demands on light-weight materials. In order to meet the challenges of the future it is vital that an emphasis be placed on tailor-making these materials to enhance specific properties. Through the use of rapid solidification processing advances have been made in our ability to engineer materials, but we have yet to be able to tailor-make a light-weight alloy with all of the characteristics we desire. A new approach to tailor-making alloys with the enhanced properties we desire is to use nonequilibrium alloying techniques such as sputter or high-rate vapor deposition to grade the structure and composition of an alloy during processing. Such alloys could be designed to take advantage of recent advances in enhancing both the mechanical properties and the corrosion resistance of Al and Mg. For conventional Al alloys, a combination of high strength and significantly enhanced corrosion resistance are mutually exclusive. In order to achieve high strengths, precipitates are necessary in the microstructure. DTIC

TRITIUM AND DECAY HELIUM EFFECTS ON THE FRACTURE TOUGHNESS PROPERTIES OF TYPES 316L, 304L AND 21Cr-6Ni-9Mn STAINLESS STEELS
M. J. Morgan and M. Tosten 1994 12 p Presented at the 5th International Conference on Hydrogen Effects on Material Behavior, Moran, WY, 11-15 Sep. 1994
(Contract DE-AC09-89SR-18035)
(DE95-001248; SRTC-MTS-94-3036; CONF-940945-2) Avail: CASI HC A03/MF A01

J-integral fracture mechanics techniques and electron microscopy observations were used to investigate the effects of tritium and its radioactive decay product, He-3, on types 316L, 304L, and 21Cr-6Ni-9Mn stainless steels. Tritium exposed and aged steels had lower fracture toughness values and shallower sloped crack-growth-resistance curves than unexposed steels. Both fracture toughness parameters decreased with increasing concentrations of He-3. The fracture toughness reductions were accompanied by a change in fracture mode from microvoid nucleation and growth processes in control samples to grain and twin boundary fracture in tritium charged and aged samples. Type 316L stainless steel had the highest fracture toughness values and type 21Cr-6Ni-9Mn had the lowest. Samples containing He-3 but degassed of tritium had fracture toughness properties that were similar to uncharged samples. The results indicate that helium bubbles enhance the embrittlement effects of hydrogen by affecting the deformation properties and by increasing localized hydrogen concentrations through trapping effects. DOE

PLASMA ARC MELTING OF TITANIUM-TANTALUM ALLOYS
P. Dunn, R. A. Patterson, and R. Haun (Retech, Inc., Ukiah, CA.) 1994 13 p Presented at the Symposium on Liquid Metal Processing and Casting, Santa Fe, NM, 11-14 Sep. 1994
(Contract W-7405-eng-36)
(DE94-016291; LA-UR-94-2409; CONF-940978-1) Avail: CASI HC A03/MF A01

Los Alamos has several applications for high temperature, oxidation and liquid-metal corrosion resistant materials. Further, materials property constraints are dictated by a requirement to maintain low density; e.g., less than the density of stainless steel. Liquid metal compatibility and density requirements have driven the research toward the Ti-Ta system with an upper bound of 60 wt% Ta-40 wt% Ti. Initial melting of these materials was performed in a small button arc melter with several hundred grams of material; however, ingot quantities were soon needed. But, refractory metal alloys whose constituents possess very dissimilar densities, melting temperatures, and vapor pressures pose significant difficulty and require specialized melting practices. The Ti-Ta alloys fall into this category with the density of tantalum 16.5 g/cc and that of titanium 4.5 g/cc. Melting is further complicated by the high melting point of Ta (3020 C) and the relatively low boiling point of Ti (3287 C). Previous electron beam melting experience with these materials resulted in extensive vaporization of the titanium and poor chemical homogeneity. Vacuum arc remelting (VAR) was considered as a melting candidate and discarded due to density and vapor pressure issues associated with electron beam. Plasma arc melting offered the ability to supply a cover gas to deal with vapor pressure issues as well as solidification control to help with macrosegregation in the melt and has successfully produced high quality ingots of the Ti-Ta alloys. DOE

MICROSTRUCTURES AND TENSILE PROPERTIES OF AS-CAST IRON-ALUMINIDE ALLOYS
S. Viswanathan, C. G. McKamey, P. J. Maziasz, and V. K. Sikka 1994 11 p Presented at the 123th Annual Meeting of the Minerals, Metals and Materials Society, San Francisco, CA, 27 Feb. - 3 Mar. 1994
(Contract DE-AC05-84OR-21400)
(DE94-017868; CONF-940204-8) Avail: CASI HC A03/MF A01

Room-temperature tensile properties of as-cast Fe3Al, Fe3Al with chromium, and Fe3Al-based FA-129 alloy have been investigated. Tensile properties have been obtained in air in the as-cast condition for all three alloys. Samples of FA-129 alloy have also been tested in oxygen and water vapor environments, and after homogenization at 700, 900, and 1200C. Transmission electron microscopy has been used to characterize ordered phases and optical metallography and scanning electron microscopy have been used to characterize the microstructure and fracture morphology. Tensile properties in the as-cast condition exhibited an environmental effect; tensile ductilities in an oxygen atmosphere were greater than those obtained in laboratory air. Homogenized samples of FA-129 alloy exhibited almost twice the ductility of the as-cast condition. Results indicate that the low ductility of as-cast Fe3Al-based alloys may be related to the relatively large grain size in the as-cast condition and the presence of the DO3 ordered phase. Microstructural characterization of the homogenized samples and comparison of the as-cast and homogenized microstructures may provide a clue to the poor ductility in the as-cast condition. DOE

OXIDE FORMATION ON NbAl3 AND TiAl DUE TO ION IMPLANTATION OF O-18
R. J. Hanrahan, Jr. (Florida Univ., Gainesville, FL.), E. D. Verink, Jr. (Florida Univ., Gainesville, FL.), S. P. Withrow, and E. O. Ristolainen (Helsinki Univ. of Technology, Espoo, Finland.) 1993 6 p Presented at the Fall Meeting of the Materials Research Society (MRS), Boston, MA, 29 Nov. - 3 Dec. 1993
(Contract DE-AC05-84OR-21400)
(DE94-017874; CONF-931108-106) Avail: CASI HC A02/MF A01

Surface modification by ion implantation of O-18 ions was investigated as a technique for altering the high-temperature oxidation of aluminide intermetallic compounds and related alloys. Specimens of NbAl3 and TiAl were implanted to a dose of 1 x 10(exp 18) ions/sq cm at 168 keV. Doses and accelerating energies were calculated to obtain near-stoichiometric concentrations of oxygen. Use of O-18 allowed the implanted oxygen profiles to be measured using secondary ion mass spectroscopy (SIMS). The near surface oxides formed were studied using x ray photoelectron spectroscopy (XPS) and Auger electron spectroscopy. Specimens were also examined using x ray diffraction and SEM. This paper presents results for specimens examined in the as-implanted state. The oxide formed due to implantation is a layer containing a mixture of Nb or Ti and amorphous Al oxides. DOE

EFFECT OF HEAT TREATMENT TEMPERATURE ON CREEP-RUPTURE PROPERTIES OF Fe3Al-BASED ALLOYS
C. G. McKamey and P. J. Maziasz 1994 12 p Presented at the Metallurgical Society Annual Meeting, San Francisco, CA, 27 Feb. - 3 Mar. 1994
(Contract DE-AC05-84OR-21400)
(DE94-017904; CONF-940286-3) Avail: CASI HC A03/MF A01

The effects of heat treatment at 1100 to 1250 C on the creep-rupture properties of an Fe3Al-based alloy were studied. Tests were conducted at 593 C (1100 F) and 207 MPa (30 ksi) in air. The modes of fracture were identified using optical metallography and scanning electron microscopy. Analytical electron microscopy was also used to study characteristics of the microstructure, including dislocations, ordered domains, and precipitates. The creep results showed maximum creep-rupture resistance with a heat treatment at approximately 1150 C, with significant decreases in rupture life after heat treatments at both lower and higher temperatures. The peak in creep life was associated with fine precipitates that were observed after the 1150 C heat treatment and persisted during prolonged creep at 593 C. Heat treatment at 1150 C appeared to cause dissolution of coarser precipitates which then reprecipitated as new fine particles upon cooling or during creep. These fine precipitates then pinned dislocations and grain boundaries to produce strength during creep. DOE

IMPROVED DIE CASTINGS THROUGH PLASMA SURFACE MODIFICATION, IMPROVED SENSORS AND DIE SOLDERING PREVENTION Quarterly Progress Report No. 1, 1 Jul. - 30 Sep. 1994
C. Mobley and J. Brevick 17 Oct. 1994 35 p
(Contract DE-FC07-94ID-13233; OSURF Proj. 729390)
(DE95-002238; DOE/ID-13233/T1) Avail: CASI HC A03/MF A01

This quarterly report covers activities of the Die Casting Research project during the period July 1, 1994 through September 30, 1994, at The Ohio State University. The objective of the Die Casting Research project is to enhance the competitiveness of the US die casting industry. To accomplish this objective, the Center for Die Casting at The Ohio State University shall perform tasks that focus on three general areas: the application of plasma surface modifications to aluminum and zinc casting dies; the development and evaluation of systems to monitor temperature, pressure, and gas content of die casting cavities; and the determination of causes of die soldering in zinc die castings. This quarterly report covers work on Task 2 -- Commercial Sensor Evaluation. DOE

MAGNETIC X RAY CIRCULAR DICHROISM IN Fe Co Pt MULTILAYERS
J. G. Tobin, A. F. Jankowski, G. D. Waddill, and P. A. Sterne (California Univ., Davis, CA.) Apr. 1994 6 p Presented at the Spring Meeting of the Materials Research Society, San Francisco, CA, 4-8 Apr. 1994
(Contract W-7405-eng-48)
(DE94-017522; UCRL-JC-115364; CONF-940411-50) Avail: CASI HC A02/MF A01

Magnetic x-ray circular dichroism in x-ray absorption has been used to investigate the ternary multilayer system, Fe Co Pt. Samples were prepared by planar magnetron sputter deposition and carefully characterized, using a variety of techniques such as grazing-incidence and high-angle x-ray scattering, Auger depth profiling and cross-section transmission electron microscopy. As previously reported, the Fe9.5 Angstrom Pt9.5 Angstrom exhibits a large dichroism in the Fe 2p absorption. Interestingly while the Co9.5 Angstrom Pt9.5 Angstrom has no measurable dichroism, the Fe4.7 Angstrom Co4.7 Angstrom Pt9.5 Angstrom sample has a dichroism at both the Fe 2p and Co 2p absorption edges. These and other results are compared to slab calculation predictions. Possible explanations are discussed. DOE

SCANNING TUNNELING MICROSCOPY STUDIES OF SELF-ASSEMBLED MONOLAYERS OF ALKANETHIOLS ON GOLD
S. J. Stranick, M. M. Kamna, K. R. Krom, A. N. Parikh, and D. L. Allara 5 Apr. 1994 16 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-91-J-1630)
(AD-A279910; TR-12) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

We have used scanning tunneling microscopy to probe the molecular scale structures of pure and mixed composition self-assembled monolayers of CH3(CH2)15SH and CH3O2C(CH2)15SH on gold. A predominant defect structure is found for both films and is assigned as a void defect in the thiolate overlayer. The mixed composition films are observed to phase segregate into domains of the pure component thiolates. Time-lapse series of scanning tunneling microscope images reveal kink-driven motion at step edges and exchange of thiolate molecules on terraces. DTIC

PROCESSING AND APPLICATIONS OF IRON ALUMINIDES
V. K. Sikka 1994 16 p Presented at the 123d Annual Meeting of the Minerals, Metals and Materials Society, San Francisco, CA, 27 Feb. - 3 Mar. 1994
(Contract DE-AC05-84OR-21400)
(DE94-017855; CONF-940204-9) Avail: CASI HC A03/MF A01

Iron aluminides are well known for their resistance to high-temperature sulfidizing and oxidizing environments. In order to take advantage of their excellent corrosion resistance, several methods for their processing have been identified. Issues with melting and processing are discussed in detail. Effects of grain size and melting practice on low-temperature ductility are also presented. Many applications for iron aluminides are described. DOE

THE EFFECT OF OXIDE INCLUSIONS ON THE KINETICS OF THE AUSTENITE TO FERRITE TRANSFORMATION IN LOW ALLOY STEEL WELD METAL
S. S. Babu, S. A. David, J. M. Vitek, and T. DebRoy (Pennsylvania State Univ., State College, PA.) 1994 5 p Presented at the International Conference on Solid-to-solid Phase Transformations in Organic Materials, Pittsburgh, PA, 17-22 Jul. 1994
(Contract DE-AC05-84OR-21400)
(DE94-018131; CONF-940704-2) Avail: CASI HC A01/MF A01

Isothermal transformation kinetics of austenite to acicular ferrite and allotriomorphic ferrite were measured in reheated low alloy steel weld deposits with similar weld compositions and austenite grain size but different inclusion characteristics. Accelerated kinetics of transformation to acicular ferrite were observed in weld metal containing coarser and titanium-rich inclusions. In contrast, kinetics of transformation to allotriomorphic ferrite were not influenced by inclusion characteristics, but, rather, by the austenite grain size and carbon concentration. DOE

IMPACT BEHAVIOR OF FeAl ALLOY FA-350

D. J. Alexander 1994 11 p Presented at the Metallurgical Society Annual Meeting, San Francisco, CA, 27 Feb. - 3 Mar. 1994
(Contract DE-AC05-84OR-21400)
(DE94-018128; CONF-940286-7) Avail: CASI HC A03/MF A01

The tensile properties and impact behavior of the iron aluminide FeAl-type alloy FA-350 (Fe-35.8Al-0.05Zr-0.24B (at. %) have been studied over the temperature range of -100 to 800 C. Half-size C harpy specimens were either oil quenched from 700 C or furnace cooled. The energy absorbed during the impact test showed a maximum value at 100 to 200 C, with decreasing energy as the temperature wasincreased, for both heat treatments. The furnace-cooled material had greater energy absorption than the oil-quenched material. The tensile tests showed increasing ductility (as measured by total elongation) with increasing temperature. The furnace-cooled material had lower strength and higher ductility than the oil-quenched material. Fractographic examination of the oil-quenched impact specimens revealed that several different fracture modes operated, depending on the test temperature. Fracture occurred by intergranular and quasicleavage fracture at low temperatures, predominantly quasicleavage at intermediate temperatures, and intergranular fracture at 800 C. For the furnace-cooled material fracture was predominantly quasicleavage at all temperatures. The higher ductility and energy absorption for the furnace-cooled material is believed to be the result of softening due to a decrease in the retained vacancy concentration. DOE

SPUTTERING OF TIN AND GALLIUM-TIN CLUSTERS

T. Lill, W. F. Calaway, Z. Ma, and M. J. Pellin 1 Aug. 1994 27 p Presented at the 10th International Workshop of Inelastic Ion-surface Collisions, Grand Targhee Resort, WY, 8-12 Aug. 1994
(Contract W-31-109-eng-38)
(DE94-018389; ANL/CHM/CP-83910; CONF-9408150-1) Avail: CASI HC A03/MF A01

Tin and gallium-tin clusters have been produced by 4 keV Ar(+) ion bombardment of polycrystalline tin and the gallium-tin eutectic alloy and analyzed by time-of-flight mass spectrometry. The sputtered neutral species were photoionized with 193 nm (6.4 eV) excimer laser light. Neutral tin clusters containing up to 10 atoms and mixed gallium-tin clusters Ga(sub (n-m))Sn(sub m) with n less than or equal to 4 for the neutrals and N less than or equal to 3 for the sputtered ionic species have been detected. Laser power density dependent intensity measurements, relative yields, and kinetic energy distributions have been measured. The abundance distributions of the mixed clusters have been found to be nonstatistical due to significant differences in the ionization efficiencies for clusters with equal nuclearity but different number of tin atoms. The results indicate that Ga2Sn and Ga3Sn like the all-gallium clusters have ionization potentials below 6.4 eV. In the case of Sn5, Sn6, GaSn and Ga(sub (n-m))Sn(sub m) clusters with n=2 to 4 and m greater than 1, the authors detect species that have sufficient internal energy to be one photon ionized despite ionization potentials that are higher 6.4 eV. The tin atom signal that is detected can be attributed to photofragmentation of dimers for both sputtering from polycrystalline tin and from the gallium-tin eutectic alloy. DOE

ON THE SPUTTERING OF METALS AND INSULATORS: A NONLINEAR EVOLUTION PROBLEM WITH NONLINEAR BOUNDARY CONDITION

Hongfei Zhang 1994 17 p
(Contract W-31-109-eng-38)
(DE95-001456; ANL/MCS/PP-71694) Avail: CASI HC A03/MF A01

In this paper the author considers a nonlinear evolution problem denoted in the paper as P. Problem (P) arises in the study of thermal evaporation of atoms and molecules from locally heated surface regions (spikes) invoked as one of several mechanisms of ion-bombardment-induced particle emission (sputtering). Then in the case of particle-induced evaporation, the Stefan-Boltzman law of heat loss by radiation is replaced by some activation law describing the loss of heat by evaporation. The equation in P is the so-called degenerate diffusion problem, which has been extensively studied in recent years. However, when dealing with the nonlinear flux boundary condition, (beta)(.) is usually assumed to be monotone. The purpose of this paper is to provide a general theory for problem P under a different assumption on (beta)(.), i.e., Lipschitz continuity instead of monotonicity. The main idea of the proof used here is to choose an appropriate test function from the corresponding linearized dual space of the solution. The similar idea has been used by many authors, e.g., Aronson, Crandall and Peletier, Bertsch and Hilhorst and Friedman. The author follows the proof of Bertsch and Hilhorst. The paper is organized as follows. They begin by stating the precise assumptions on the functions involved in P and by defining a weak solution. Then, in Section 2 they prove the existence of the solution by the method of parabolic regularization. The uniqueness is proved in Section 3. Finally, they study the large time behavior of the solution in Section 4. DOE

THE MATERIALS CORROSION AND ENVIRONMENTAL EFFECTS LABORATORY (MCEL)

D. P. Butt 1994 3 p Presented at the 19th DOE Conference on Compatibility, Aging and Service Life, Los Alamos, NM, 28-30 Sep. 1994
(Contract W-7405-eng-36)
(DE94-018268; LA-UR-94-2731; CONF-9409181-5) Avail: CASI HC A01/MF A01

A new materials corrosion laboratory has been set up, based primarily in the Materials Science Laboratory (MSL) at Los Alamos National Laboratory. The mission of the laboratory is to conduct basic and applied research in order to rapidly evaluate the durability and useful life of materials considered for use in severe environments. The laboratory serves and provides facilities for industry and universities, and researchers from the present and future DOE complex. The primary customers within the DOE complex are those concerned with materials compatibility or durability problems associated with the safety and long term storage of nuclear weapons and waste, transmutation of nuclear waste, and high temperature corrosion and compatibility in energy systems. The general technical objective of MCEL is to identify the causes and mechanisms of corrosion processes or component failures, quantitatively determine corrosion rates or mechanisms, and help the customer adopt appropriate strategies (such as new materials selection, process modification, new inspection methods, anodic or cathodic protection, or the use of coatings or inhibitors) for effective corrosion prevention. To accomplish its technical objectives, MCEL provides both experimental and theoretical analytical approaches to solving corrosion problems. The following is a description of some of the capabilities of the laboratory and personnel. DOE

MAGNETIC EXCITATIONS IN MODULATED PrNi2Si2

J. A. Blanco (Universidad de Oviedo, Gijon, Spain.), R. M. Nicklow, and D. Schmitt (Centre National de la Recherche Scientifique, Grenoble, France.) 1994 11 p Presented at the International Conference on Magnetism, Warsaw, Poland, 22-26 Aug. 1994
(Contract DE-AC05-84OR-21400)
(DE95-001077; CONF-940819-4) Avail: CASI HC A03/MF A01

The magnetic excitations in a single crystal of PrNi2Si2 have been studied by inelastic neutron scattering. Dispersion curves have been followed through the centered tetragonal Brillouin zone. In the paramagnetic phase, at 39 K, the lowest energy magnetic branch exhibits an important dispersion ranging from 1.9 to 3.5 meV, the minimum energy occuring at the wave vector of the ordered phase; from the observed dispersion the inter-ionic isotropic bilinear exchange parameters are deduced. At 4.2 K, in the modulated phase, the same branch presents a dispersion slightly larger, but not significantly different. DOE

FEASIBILITY STUDY OF POWER GENERATION SYSTEM WITH SHAPE MEMORY ALLOYS

Mar. 1994 69 p In JAPANESE
(DE95-714802; NEDO-P-9324) Avail: CASI HC A04/MF A01

The power generation system to use shape memory alloys which operate at temperatures below 100C was conceptually designed and studied in feasibility to amplify the utilization of low temperature energy so far not utilized yet. The energy conversion efficiency of shape memory alloy is

0.7% to 9% per strain of 1% to 8%, so that it has a possibility of being utilized as an energy conversion element. The Ni-Ti alloy excels all the other shape memory alloys in shape recovery stability and corrosion resistivity. The heat engines presently proposed are of four types, i.e., offset crank type, differential pulley turbine type, tilting plate type and piston type. If the deformation strain and life of alloy are taken into consideration, the utilization is highly possible for the piston type heat engine. As a power generation system, engineered is the method in which low temperature waste heat is effectively utilized with an introduction of energy accumulation and storage system. Possibly made structurally compact, the energy conversion part with shape memory alloy is costwise so low that its use has a high feasibility. DOE

MOESSBAUER STUDY OF THE SINTERED Mn(0.70)Zn(0.23)Fe(2.07)O4

Dingzhang Li (Shanxi Univ., China.), Yuying Duan (Shanxi Province Inst. of Traditional Chinese Medicine, China.), and Zhenli Zhang (Institute of Magnetic Recording Technology, Taiyuan, China.) Aug. 1993 9 p
(DE94-631462; CNIC-00771; SU-0001) Avail: CASI HC A02/MF A01
(US Sales Only)

The samples of Mn-Zn ferrite having characteristic of low power expense, were obtained. Its structure and phase transformation in pre-sintering process by means of Moessbauer spectroscopy were studied. The conclusions are as follows: (1) The sample sintered at high temperature contains excess iron, has the typical Moessbauer parameters. Its formula can be written as Mn(0.70)Zn(0.23)Fe(2.07)O4. (2) The doublet sub-spectrum arise during thermal transformation varies with the process of the phase transformation. It serves as a mark of the course of the transformation. (3) The pre-sintering temperature 1040 C has primarily approached to the earlier stage of phase transformation to form Mn-Zn ferrite. (4) The breaks in heating and pre-sintering repeatedly at low temperature are unfavorable to phase transformation. (5) The Moessbauer parameters of the raw material Fe2O3 are markedly different from that in literature. There is obvious influence on the samples pre-sintered but little influence on the sample sintered at high temperature. DOE

THERMODYNAMIC ANALYSIS OF STABLE AND METASTABLE EQUILIBRIUM DIAGRAMS OF THE Cu-Cr SYSTEM

Kejun Zeng and Marko Haemaelaeinen 1994 24 p
(ISSN 0785-5168)
(PB95-127775; TKK-V-B87; ISBN-951-22-1923-9) Avail: CASI HC A03/MF A01

The available experimental information is not sufficient to determine the temperature dependence of excess Gibbs energy of the liquid Cu-Cr alloys. The previously optimized excess entropy of mixing of the liquid phase is too positive. A new set of optimized thermodynamic functions of the Cu-Cr system has been obtained from thermodynamic and phase diagram data incorporating the latest ones. The Tanaka-Gokcen-Morita relationship was used to constraint the excess enthalpy and entropy coefficients of the liquid phase. The optimized thermodynamic functions can account very well for the process of precipitation in the supersaturated fcc Cu-Cr alloys. NTIS

NITROGEN ALLOYED MARTENSITIC STEELS

Jyrki Romu, Yong Liu, and Hannu Haenninen May 1994 116 p
(PB95-127791; ISBN-951-22-2135-7) Avail: CASI HC A06/MF A02

The demand of materials having a combination of high strength, good toughness and good corrosion resistance at both low and high temperatures has led to the development of nitrogen alloyed martensitic steels. In these steels carbon is replaced completely or partially with nitrogen. Nitrogen and chromium improve corrosion resistance of martensitic steels. High strength in combination with good toughness is due to the small grain size of the steels and fine and finely distributed nitrides/carbonitrides, which are formed by proper heat treatments of these steels. Nitrides/carbonitrides are formed during tempering heat treatment, when a pronounced secondary hardening effect takes place. Wear resistance of martensitic steels can be improved by proper alloying of nitrogen and nitride forming elements. NTIS

METASTABLE BCC PHASE FORMATION IN THE Nb-Cr-Ti SYSTEM

D. J. Thoma and J. H. Perepezko (Wisconsin Univ., Madison, WI.) 1994 8 p Presented at the ISMANAM-1994, Grenoble, France, 27 Jun. - 1 Jul. 1994
(Contract W-7405-eng-36)
(DE94-016212; LA-UR-94-2528; CONF-9406229-1) Avail: CASI HC A02/MF A01

Metastable disordered bcc phases have been formed from the melt in the Nb-Cr-Ti system where primary Laves phases would develop under equilibrium solidification conditions. Three vertical temperature-composition sections in the ternary system incorporating NbCr, were evaluated: the Nb-Cr binary, the TiCr2-NbCr2 isoplethal section, and the NbCr2-Ti plethal section. In the rapid solidification of NbCr2, metastable bcc phase formation was not observed, but deviations from NbCr2 stoichiometry or alloying with Ti was found to promote bcc phase formation by decreasing the required liquid undercooling to reach the metastable bcc liquidus and solidus. The metastable phases were characterized through x-ray diffraction (XRD), and systematic deviations from Vegard's Rule have been defined in the three plethal sections. The metastable bcc phases decompose at temperatures greater than 800 C to uniformly refined microstructures. As a result, novel microstructural tailoring schemes are possible through the metastable precuror microstrucures. DOE

N95-21238# Los Alamos National Lab., NM.

TRIBOLOGY AND SURFACE MECHANICAL PROPERTIES OF EXCIMER LASER NITRIDED TITANIUM

T. R. Jervis, J. P. Hirvonen (Technical Research Centre of Finland, Espoo, Finland.), T. G. Zocco, and J. R. Tesmer 1994 11 p Presented at the Fall Meeting of the Materials Research Society, Boston, MA, 28 Nov. - 2 Dec. 1994
(Contract W-7405-eng-36)
(DE95-002751; LA-UR-94-3656; CONF-941144-1) Avail: CASI HC A03/MF A01

The authors have nitrided Ti-6Al-4V alloys using excimer laser pulses at 1.2 J/sq cm in high purity N2 at approximately one atmosphere. Substantial nitrogen and some oxygen incorporation resulted from multiple pulse processing. Formation of a TiN surface film was not observed. They have examined the tribological and mechanical properties of these surfaces using pin-on-disk and nanoindenter techniques respectively. Nitrogen alloying results in reduced friction and torque noise in the pin-on-disk measurements.

At higher N concentrations, very little wear is observed, even after the friction behavior suggests surface deterioration. This is consistent with the formation of a transfer film at the sliding interface. Nanoindenter measurements of the surfaces show increasing hardness proportional to nitrogen incorporation. The tribological improvements can therefore be ascribed to a combination of increased surface hardness and tribochemical effects. DOE

METHODS OF MEASURING ADHESION FOR THERMALLY GROWN OXIDE SCALES
P. Y. Hou and A. Atkinson (AEA Technology, London, England.) Jun. 1994 25 p Presented at the Workshop on Mechanical Properties of Protective Oxide Scales, Teddington, England, 20-22 Jun. 1994
(Contract DE-AC03-76SF-00098)
(DE94-018177; LBL-35741; CONF-9406247-1) Avail: CASI HC A03/MF A01

High temperature alloys and coatings rely on the formation of adherent scales to protect against further oxidation, but scale spallation is often problematic. Despite the technical importance of the problem, 'practical adhesion', which refers to the separation of the oxide from the metal, has mainly been treated qualitatively in the past. Various techniques now exist such that the subject can be assessed in quantitative or semiquantitative terms. Some of the techniques are described, and their weakness and strength are discussed. The experimental methods addressed here include: tensile pulling, micro-indentation, scratch test, residual stress induced delamination, laser or shock wave induced spallation, double cantilever beam and several four-point beam bending approaches. To date, there is not a universal, easy test for oxide adhesion measurement that can provide reproducible information on interfacial fracture energy for a variety of oxide/metal systems. Much experimentation is still needed to increase confidence in many of the existing tests, and the fundamental mechanics for some present techniques also require further development. DOE

PLASTIC DEFORMATION OF ORDERED INTERMETALLIC ALLOYS: FUNDAMENTAL ASPECTS
M. H. Yoo (Max-Planck-Inst. fuer Eisenforschung, Duesseldorf, Germany.) 1994 12 p Presented at the 6th International Symposium on Plasticity of Metals and Alloys, Prague, Czechoslovakia, 5-9 Sep. 1994
(Contract DE-AC05-84OR-21400)
(DE95-001070; CONF-9409227-1) Avail: CASI HC A03/MF A01

Fundamental aspects of plastic deformation in ordered intermetallic alloys are reviewed by directly comparing the temperature-dependent yield stresses of Ni3Al and Ni3Si (the L12 structure), NiAl and FeAl (the B2 structure), and TiAl and Ti3Al (non-cubic L1(sub 0) and D0(sub 19) structures, respectively). While the yield strength anomaly observed in Ni3Al is consistent with the prevailing dislocation models, that found in stoichiometric Ni3Si is not. The strong plastic anisotropy observed in NiAl stems from the high antiphase boundary energy, and that found in two-phase (gamma)-TiAl/(alpha)(sub 2)-Ti3Al is due to the exceptionally high compressive yield strength along the c-axis of Ti3Al. THEORETICAL-EXPERIMENTAL STUDY ON THE ELECTROSLAG REMELTING TECHNOLOGY OF HIGH QUALITY STEELS Ph.D. Thesis [ESTUDIO TEORICO EXPERIMENTAL DE LA TECNOLOGIA DE REFUSION BAJO ESCORIA ELECTROCONDUCTORA DE ACEROS FINOS]
Eduardo Francisco RoblesPiedras 1993 234 p In SPANISH
(DE94-629216; INIS-MF-13927) Avail: CASI HC A11/MF A03 (US Sales Only)

This is a theoretical-experimental laboratory study on the electroslag remelting technology (ESRT) of high quality steels. The objective of this study was to analyze the problems that this technology entails and thus facilitate its industrial application in Mexico. The study was carried out using a 1 kg capacity furnace. The behavior of different fluxes on the remelting of 1018 AISI carbon steel was established and a slag 70F/15/15 was selected for the remelting of H-13 AISI hot work tool steel. From the experimental results it was possible to establish a flux manufacture route, the electrode conditioning necessary for the experiments, and the critical points of the process. It was demonstrated that the crucible and electrode advance system are the more critical points in the furnace manufacture, that the start up is fundamental for the remelting continuity, and that the CaF2 base slags are more recommendable for special steels refining. It has been proven that it is possible to experiment with little laboratory electroslag furnaces. DOE

EFFECT OF NEUTRON IRRADIATION ON THE IMPACT PROPERTIES OF A533B STEEL
Lonnie E. Schubert (Missouri Univ., Rolla, MO.), Arvind S. Kumar (Missouri Univ., Rolla, MO.), Stan T. Rosinski, and Margaret L. Hamilton (Pacific Northwest Lab., Richland, WA.) 1994 16 p Presented at the 17th Symposium on Effects of Radiation on Materials, Sun Valley, ID, 20-23 Jun. 1994
(Contract DE-AC04-94AL-85000)
(DE95-001834; SAND-94-1539C; CONF-940657-6) Avail: CASI HC A03/MF A01

A new methodology is proposed to correlate the upper shelf energy (USE) of full size and subsize Charpy specimens of a nuclear reactor pressure vessel plate material, ASTM type A 533 Grade B (A533B) having a low USE (USE less than 100 J). The methodology appears to be more satisfactory than those methodologies proposed earlier. The USE was normalized by a normalization factor involving the dimensions of the Charpy specimen, the elastic stress concentration factor, and the plastic constraint at the notch root. The normalized values of the USE were found to be invariant with specimen size. In addition, it was also found that the ratio of the USE of unirradiated to that of irradiated materials was approximately the same for full, half, and third size specimens. The ductile-to-brittle transition temperature (DBTT) increased due to irradiation at 150 C to a nominal fluence of 1.0 x 10(exp 19) n/sq cm (E greater than 1 MeV) by 78 C, 83 C, and 70 C for full, half, and third size specimens, respectively. These shifts in DBTT appeared to be independent of specimen size and notch geometry. DOE

COMPUTATIONAL MODELING OF DIFFUSION-CONTROLLED TRANSFORMATIONS IN TERNARY SYSTEMS
J. M. Vitek, S. A. Vitek, and S. A. David 1994 7 p Presented at the International Conference on Solid-to-solid Phase Transformations in Organic Materials, Pittsburgh, PA, 17-22 Jul. 1994
(Contract DE-AC05-84OR-21400)
(DE95-001358; CONF-940704-4) Avail: CASI HC A02/MF A01

The diffusion-controlled solid-state transformation between two phases in a ternary system was modeled using an implicit finite difference method. The one-dimensional system that was modeled was of finite size, and the interface the two phases was allowed to move. Equilibrium at the interface was assumed, and a grid that moved with the interface was utilized. The calculations were applied to the iron-nickel-chromium ternary system to model the growth or dissolution of ferrite in an austenitic stainless steel weld at elevated temperatures. The equilibrium conditions at the interface were specified with the aid of the ThermoCalc(trademark) software program that was used to calculate tie-line compositions as a function of overall alloy composition and temperature. Appropriate parameters for the analysis were chosen based on an earlier parametric study. Calculations were made for the isothermal transformation kinetics over a range of temperatures from 973 to 1573 K, in which the behavior varied from complete dissolution of the ferrite to growth of ferrite at the expense of austenite. The variation in ferrite size and composition often was quite complicated and frequently did not follow a direct path from the initial condition to the final equilibrium. Additional calculations were carried out for non-isothermal aging at constant cooling rates from 1573 to 973 K. The computational routine can be applied to any diffusion-controlled transformation in a ternary system with any thermal history, provided suitable data for the equilibrium at the interface is available. ANALYSIS OF WELDS ON HELIUM-CONTAINING RESTRAINT TEST PLATES
W. R. Kanne, Jr. and G. T. Chandler Sep. 1994 30 p
(Contract DE-AC09-89SR-18035)
(DE95-001809; WSRC-TR-94-0449) Avail: CASI HC A03/MF A01

Over the last several years, Savannah River has had the goal of developing a repair process and the technical understanding necessary to make weld repairs on stainless steel containing helium. This report documents the results of a series of test welds made with varying amounts of mechanical restraint on type 304 stainless steel containing helium from tritium decay. This change in restraint produced different states of stress on the weld area during welding. The test welds were either overlay welds or weave beads. The amount of heat affected zone cracking observed in the welds provided the primary, analysis tool for evaluating the tests. Generally, higher restraint produced greater cracking of the welds. These results, along with previous Savannah River data, indicate that in a practical application of a repair method for helium-containing stainless steel, the effect of part configuration must be considered, as well as the type of weld, to reduce stresses that can cause helium embrittlement cracking. THEORETICAL STUDY OF THE NOBLE METALS ON SEMICONDUCTOR SURFACES AND TI-BASE SHAPE MEMORY ALLOYS Ph.D. Thesis
Yungui Ding 27 Jul. 1994 122 p
(Contract W-7405-eng-82)
(DE95-001654; IS-T-1689) Avail: CASI HC A06/MF A02

The electronic and structural properties of the (radical 3 x radical 3) R30 degrees Ag/Si(111) and (radical 3 x radical 3) R30 degrees Au/Si(111) surfaces are investigated using first principles total energy calculations. We have tested almost all experimentally proposed structural models for both surfaces and found the energetically most favorable model for each of them. The lowest energy model structure of the (radical 3 x radical 3) R30 degrees Ag/Si(111) surface consists of a top layer of Ag atoms arranged as 'honeycomb-chained-trimers' lying above a distorted 'missing top layer' Si(111) substrate. The coverage of Ag is 1 monolayer (ML). We find that the honeycomb structure observed in STM images arise from the electronic charge densities of an empty surface band near the Fermi level. The electronic density of states of this model gives a 'pseudo-gap' around the Fermi level, which is consistent with experimental results. The lowest energy model for the (radical 3 x radical 3) R30 degrees Au/Si(111) surface is a conjugate honeycomb-chained-trimer (CHCT-1) configuration which consists of a top layer of trimers formed by 1 ML Au atoms lying above a 'missing top layer' Si(111) substrate with a honeycomb-chained-trimer structure for its first layer. The structures of Au and Ag are in fact quite similar and belong to the same class of structural models. However, small variation in the structural details gives rise to quite different observed STM images, as revealed in the theoretical calculations. The electronic charge density from bands around the Fermi level for the (radical 3 x radical 3) R30 degrees, Au/Si(111) surface also gives a good description of the images observed in STM experiments. First principles calculations are performed to study the electronic and structural properties of a series of Ti-base binary alloys TiFe, TiNi, TiPd, TiMo, and TiAu in the B2 structure. DOE

DYNAMIC NMR STUDIES OF RESTRICTED ARENE ROTATION IN THE CHROMIU TRICARBONYL THIOPHENE AND SELENOPHENE COMPLEXES Ph.D. Thesis
M. J. Sanger 27 May 1994 98 p
(Contract W-7405-eng-82)
(DE95-001656; IS-T-1698) Avail: CASI HC A05/MF A02

This thesis contains the results of organometallic studies of thiophene and selenophene coordination in transition metal complexes. Chromium tricarbonyl complexes of thiophene, selenophene, and their alkyl-substituted derivatives were prepared and variable-temperature C-13 NMR spectra of these complexes were recorded in dimethyl ether. Bandshape analyses of these spectra yielded activation parameters for restricted rotation of the thiophene and selenophene ligands in these complexes. Extended Hueckel molecular orbital calculations (EHMO) of the free thiophene and selenophene ligands and selected chromium tricarbonyl thiophene complexes were performed to better explain the activation barriers of these complexes. The structure of Cr(CO)3((eta)(sup 5)-2,5-dimethylthiophene) was established by a single crystal X-ray diffraction study. DOE

CORROSION EVALUATION OF FUEL CANISTER CRUSHER RIGGING
Carolyn E. Graves 2 Nov. 1994 20 p
(Contract DE-AC06-87RL-10930)
(DE95-002962; WHC-SD-SNF-ER-004) Avail: CASI HC A03/MF A01

A fuel canister crusher with attached rigging is located in the 105 K-East Basin discharge chute. This equipment is slated to be moved as part of seismic mitigation to prevent a major basin leak through a construction joint located in the base of the chute. This corrosion analysis assessed the load-bearing ability of the rigging, which consists of shackles and thimble-spliced wire rope. The K-East Basin demineralized water results in corrosion rates of less than 2 mil/year (less than 0.05 mm/year) for carbon, low-alloy carbon, and stainless steels. The galvanized carbon steel shackles (with low-alloy steel anchor pins) have experienced negligible corrosion and are judged to be mechanically unaffected by their water exposure. The carbon steel wire rope and stainless steel thimbles have undergone minimal corrosion. Due to the small amount of corrosion products (as seen from video inspection), the absence of wire breakage, and a Factor of Safety calculation, it is judged that the wire rope and thimbles would withstand the proposed relocation activities. DOE

SIMULATIONS OF METAL DISSOLUTION AND CORROSION
P. C. Searson 1994 14 p
(Contract DE-FG02-89ER-45388)
(DE94-019295; DOE/ER-45388/T2) Avail: CASI HC A03/MF A01

The control of metal dissolution processes is important in fields ranging from battery technology to corrosion. Nevertheless, metal dissolution remains a poorly understood class of electrochemical reactions. Although the reaction sequences for dissolution of many metals have been elucidated, kinetic descriptions are based on area averaged values of parameters that describe the relationship between the rate of reaction and the activation energy. Theoretical and experimental research on metal dissolution has focused traditionally on macroscopic processes and features. However, in the last few years there has been considerable interest in examining these processes on a microscopic scale. In addition, the growth and formation of rough interfaces is of considerable practical importance in surface science and many similarities can be found between material removal processes (e.g. etching, evaporation, and erosion) and material addition processes (e.g. crystal growth, condensation, vapor deposition, and electrodeposition). Over the next few years, results from theoretical modeling of dissolution processes, in conjunction with new experimental techniques such as in situ scanning tunneling microscopy, are expected to provide a new insight into the processes controlling metal dissolution and corrosion. The objectives of this program were to determine the relationship between dissolution kinetics and surface morphology for metal dissolution and corrosion processes. Specific objectives include determination of: (1) the relationship between surface morphology and applied potential; (2) site population statistics and the contribution of different sites to the total dissolution rate; and (3) the role of surface diffusion in dissolution processes. WELDABILITY OF IRON ALUMINIDES
G. M. Goodwin, C. J. McKamey, P. J. Maziasz, and V. K. Sikka 1993 9 p Presented at the 7th Annual Conference on Fossil Energy Materials, Oak Ridge, TN, 11-13 May 1993
(Contract DE-AC05-84OR-21400)
(DE94-019114; CONF-9305135-11) Avail: CASI HC A02/MF A01

Corrosion-resistant, weldable iron-aluminide alloys with improved high-temperature strength are being developed for structural applications, and for weld overlay cladding of conventional structural steels and alloys.

The weld hot cracking of iron-aluminide alloys is highly variable to over a wide range of aluminum content. In general, the higher aluminum content alloys are somewhat more resistant to hot cracking, and by careful choice of alloying additions (and balancing of multiple additions), cracking resistance equivalent to commercial austenitic stainless steels can be achieved. Improved weldability, however, often comes at the expense of high-temperature strength. Delayed cold cracking, presumed to be hydrogen-related, is also an important consideration in welding these alloys, either as monolithic materials, or as weld overlay cladding on stainless or low alloy steel substrates. The authors are employing various combinations of preheat and postweld stress relief heat treatments to assess the severity of this problem, and have determined that heat treatment in excess of 400 C following welding will be required to avoid delayed cracking. Due to the difficulties encountered in fabricating some of the alloy compositions into wire or rod, they are also pursuing the formulation of coated electrodes for use in shielded metal-arc (SMA) welding. Initial attempts have shown very high aluminum losses in the welding arc, and additional batches of electrodes are being formulated and produced. DOE

FINITE ELEMENT MODELLING OF CREEP CRACK GROWTH IN 316 STAINLESS AND 9Cr-1Mo STEELS
P. Krishnaswamy and Frederick W. Brust, Jr. 1994 15 p Presented at the 11th International Invitational Symposium on the Unification of Analytical, Computational, and Experimental Solution Methodologies, Danvers, MA, 18-20 Aug. 1993
(Contract DE-FG02-90ER-14135)
(DE94-018977; CONF-9308138-4) Avail: CASI HC A03/MF A01

The failure behavior of steels under sustained and cyclic loads has been addressed. The constitutive behavior of the two steels have been represented by the conventional strain-hardening law and the Murakami-Ohno model for reversed and cyclic loads. The laws have been implemented into the research finite element code FVP. Post processors for FVP to calculate various path independent integral fracture parameters have been written. Compact tension C(T) specimens have been tested under sustained and cyclic loads with both the load point displacement and crack growth monitored during the tests. FE models with extremely refined meshes for the C(T) specimens were prepared and the experiment simulated numerically. Results from this analysis focus on the differences between the various constitutive models as well as the fracture parameters in characterizing the creep crack growth of the two steels. DOE

A NEW UNIVERSAL SOLUTION FOR THE ELECTROFINISHING OF METALLIC MATERIALS
T. W. Ellis, T. A. Lograsso, S. Hilsenbeck, and H. E. Sailsbury 1994 7 p Presented at The Metallurgical Society (TMS) Conference on High Performance Composites, Rosemont, IL, 10-15 Oct. 1994
(Contract W-7405-eng-82)
(DE95-001681; IS-M-795; CONF-9410184-4) Avail: CASI HC A02/MF A01

A new reagent has been applied to the electrofinishing of metallic materials for metallographic preparation and surface cleaning. The development of this reagent was in response to the safety, health, and disposal problems associated with the use of perchloric acid based solutions. This procedure has been applied to metallic materials that are very difficult to electrofinish, e.g., rare earths, Ti, Nd2Fe14B, Pb, and intermetallic alloys. Both the procedure and results of electrofinishing will be discussed. DOE

(Contract N00014-92-C-0214)
(AD-A279066; MML-TM-94-10) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The first full-sized actuator module has been fabricated. The first actuator was sintered using the sintering profile of the 3/4-sized actuator module (5 C/min to 900 C, 1 hour hold, 1 C/min to 1200 C, 3 hour hold, 1 C/min to 500 C to room temperature). This actuator cracked during sintering. The sintering schedule was once again slowed down for the second actuator module (5 C/min to 500 C, 2 C/min to 900 C, hold 1 hour, 1 C/min to 1200 C, hold 3 hours, 1 C/min to room temperature), and as a result, we were able to fabricate our first full-sized actuator module without cracks. One full-sized actuator module is out of burnout and is awaiting sintering. Two 3/4-sized actuator modules have survived sintering without cracks. We plan to use these to help set-up our polishing and testing procedures for the full-sized actuators. DTIC

CONSEQUENCES OF OSCILLATORY POTENTIALS AND ANGULAR FORCES IN TRANSITION METALS AND THEIR ALUMINIDES
A. E. Carlsson (Washington Univ., Saint Louis, MO.), J. Zou, and R. Phillips (Cornell Univ., Ithaca, NY.) 1994 10 p Presented at the Materials Week 1993, Pittsburgh, PA, 17-21 Oct. 1993
(Contracts DE-AC05-84OR-21400; DE-FG02-84ER-45130)
(DE94-019127; CONF-9310224-3) Avail: CASI HC A02/MF A01

The authors discuss two applications of recently developed potential-energy functions. The first application involves 'constant-volume' type potentials for Al-rich transition-metal compounds and alloys. Using a combination of Green's function analysis and pseudopotential perturbation theory, a set of potentials suitable for atomistic simulations is derived. These are used to study the structural energetics of Al-Co and to analyze the origins of quasicrystallinity and complex phases in Al-Mn. The second type of applications treats the energetics of small atomic clusters using angular forces based on the 'mu(sub 4)' methodology. Calculations using a d-band model fitted to W suggest that the lowest-energy state for a four-body W cluster is a rhombus, rather than the normally expected tetrahedron. DOE

RELATIONSHIP BETWEEN DENDRITE COHERENCY AND CASTABILITY OF SOME COMMERCIAL FOUNDRY ALLOYS
A. K. Dahle and L. Arnberg 18 Mar. 1994 29 p
(PB95-110243; STF24-A94558) Avail: Issuing Activity (National Technical Information Service (NTIS))

The castability of different commercial Al-Si foundry alloys have been practically evaluated in a foundry. Although some of the alloys were similar in composition, they showed large differences in castability. The dendrite coherency points have been determined from remelted samples of these alloys. A relationship is observed for some alloys, where a decrease in castability is related to a slightly earlier coherency point. The other alloys showed fading, most probable due to loss of a eutectic modifying element, which prevents any conclusions. Metallographic samples have been investigated for verification. NTIS

SHEET METAL FORMABILITY
O. Daaland 12 Apr. 1994 28 p
(PB95-110250; STF24-A94572) Avail: Issuing Activity (National Technical Information Service (NTIS))

By definition, sheet metal forming is the process of converting a flat sheet of metal into a part of desired shape without fracture or excessive localized thinning. The ability to produce a variety of shapes from flat sheets of metal at high rates of production has been one of the real technological advances of the twentieth century. This transition from hand-forming operations to mass-production methods has been an important factor in the great improvement in the standard of living which occurred during the period. The production of useful shapes by plastic deformation is presented in this lecture. NTIS

FRACTURE BEHAVIOR OF THE Fe-8Al ALLOY FAP-Y
D. J. Alexander 1994 11 p Presented at the 8th Annual Conference on Fossil Energy Materials, Oak Ridge, TN, 10-12 May 1994
(Contract DE-AC05-84OR-21400)
(DE95-000956; CONF-9405143-8) Avail: CASI HC A03/MF A01

The tensile and impact properties of two heats of the reduced aluminum alloy FAP-Y have been measured and compared to the Fe3Al alloy FA-129. The FAP-Y material has similar yield strengths up to 400 C, and much better ductility and impact properties, as compared to the FA-129. Despite excellent room-temperature ductility, the ductile-to-brittle transition temperature is still quite high, around 150 C. The material is found to be strain-rate sensitive, with a significant increase in the yield strength at strain rates of about 10(exp 3) s(exp -1). It is believed that this strain-rate sensitivity is responsible, at least in part, for the high ductile-to-brittle transition temperature. DOE

AIRCRAFT CORROSION STUDY Final Report
J. T. Stropki and R. D. Smith Dec. 1993 62 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract F09603-90-D-2217)
(AD-A279527; CGR/DC-01/94; USCG-D-05-94) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

A comparison of the test results obtained for the unaged French and 2024-T3 (bare and hard anodized) alloys suggests that the resistance of all materials to raindrop erosion is identical. Superior performance of the hard anodized Alloy 2024-T3 sample was not observed during the erosion testing. Post-test examinations of the hard anodized 2024-T3 sample indicate that the performance of the coating was limited by spalling of the coating from the substrate. A review of the literature suggests that this condition is due to abnormal surface roughness of the anodic coating. This condition, which can be minimized with the application of silicone waxes (or similar surface treatments) to the coated surfaces, does contribute to poor chemical and impact resistance. No pretest surface characterizations were performed on this material. In summary, the results of this program suggest that Alloy 2024-T3 be considered as a candidate replacement material for the French alloy that is currently being used on the outer wing slats of the HU-25A aircraft. HYDROGENATION OF NITRILES ON A WELL-CHARACTERIZED NICKEL SURFACE: FROM SURFACE SCIENCE STUDIES TO LIQUID PHASE CATALYTIC ACTIVITY MEASUREMENTS Ph.D. Thesis
D. E. Gardin Dec. 1993 187 p
(Contract DE-AC03-76SF-00098)
(DE94-018184; LBL-35914) Avail: CASI HC A09/MF A02

Nitrile hydrogenation is the most commonly used method for preparing diverse amines. This thesis is aimed at the mechanism and factors affecting the performance of Ni-based catalysts in nitrile hydrogenations. Surface science techniques are used to study bonding of nitriles and amines to a Ni(111) surface and to identify surface intermediates. Liquid-phase hydrogenations of cyclohexene and 1-hexene on a Pt foil were carried out successfully. Finally, knowledge about the surface structure, surface chemical bond, dynamics of surface atoms (diffusion, growth), and reactivity of metal surfaces from solid-gas interface studies, is discussed. METHODS AND OPPORTUNITIES IN THE RECYCLING OF RARE EARTH BASED MATERIALS
T. W. Ellis, F. A. Schmidt, and L. L. Jones 1994 8 p Presented at The Metallurgical Society (TMS) Conference on High Performance Composites, Rosemont, IL, 10-15 Oct. 1994
(Contract W-7405-eng-82)
(DE95-001680; IS-M-796; CONF-9410184-5) Avail: CASI HC A02/MF A01

Rare Earth based materials are increasingly being utilized in industrial and commercial practice. Large volume production of permanent magnet materials, $Nd_2Fe_{14}B$, $SmCo_5$, Sm_2Co_{17}, and rechargeable Ni/Metal Hydride batteries, $LaNi_5$, has increased the amount of rare earth based materials in the waste stream. Both for economic and environmental reasons, recycling and reuse of all materials is desirable. Unfortunately, the recycling methodology for these materials is in its infancy. In this paper the present 'state of the art', in recycling of rare earth based materials will be discussed. Additionally, new methods which alleviate many of the concerns of present aqueous based recycling technology will be presented. DOE

CORROSION RESISTANCE AND BEHAVIOR OF CONSTRUCTION MATERIALS EXPOSED TO DILUTE SULFURIC ACID AT ELEVATED TEMPERATURES UNDER STATIC CONDITIONS
D. T. Nguyen 1994 18 p
(DE95-001723; Z-332) Avail: CASI HC A03/MF A01

Laboratory investigation has been undertaken to determine the electrochemical behavior and corrosion resistance of various construction materials in a simulated hydrolysis environment (5 wt % sulfuric acid) at temperatures ranging from 90 to 220C. Tests were performed in an autoclave-type electrochemical cell. The corrosion behavior of the test materials was determined using computer-controlled DC potentiodynamic polarization. Corrosion rates of the test materials were determined using AC impedance techniques. Among the stainless steels tested, only alloy N08026 (Carpenter 20Mo-6) performed satisfactory up to a temperature of 100C. The alloy passivated spontaneously in the environment and corroded at a rate of less than 2 mpy. None of the stainless steels tested could be used at 120C or above. A number of nickel-based alloys tested had good corrosion resistance up to 100C, but their corrosion rate exceeded 2 mpy at higher temperatures. Zirconium alloys were satisfactory up to 180C. Only tantalum and a tantalum-niobium alloy were satisfactory up to 220C. DOE

N95-21740 Tennessee Valley Authority, Muscle Shoals, AL.
CORROSION RESISTANCE AND BEHAVIORAL CHARACTERISTICS OF METALS EXPOSED TO 70 PERCENT BY WEIGHT SULFURIC ACID AT ELEVATED TEMPERATURES
D. T. Nguyen and G. E. Farina 1994 13 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE95-001724; Z-333) Avail: CASI HC A03

The development of a concentrated acid hydrolysis process may necessitate the storage, handling, and processing of concentrated solution of sulfuric acid at temperatures in excess of 70C. Due to the corrosivity of the sulfuric acid at elevated temperatures, a series of corrosion tests was conducted to determine the corrosion performance and behavior of various construction materials using immersion and electrochemical techniques. Test results showed that among the stainless steels tested, only Carpenter 20Mo-6 performed satisfactorily up to 70C. It passivated spontaneously and corroded at a rate less than 40 (mu)m/yr (1.6 mpy). Among numerous nickel-based alloys tested, only Hastelloy B-2 had excellent corrosion resistance up to 100C with a corrosion rate less than 50 (mu)/yr (2 mpy), although the alloy did not passivate. Zirconium alloy Zr 702 provided excellent corrosion resistance to 100C. The alloy passivated spontaneously, but its passive range decreased, evidently with increase in temperature. Tantalum and KBI-40 provided excellent corrosion protection at all test temperatures. The materials passivated spontaneously with a wide passive range. DOE

PLASMA-INDUCED-DAMAGE OF GaAs DURING ETCHING OF REFRACTORY METAL CONTACTS
R. J. Shul, M. L. Lovejoy, A. G. Baca, J. C. Zolper, D. J. Rieger, M. J. Hafich, R. F. Corless, and C. R. Vartuli (Florida Univ., Gainesville, FL.) 1994 18 p Presented at the 41st Annual American Vacuum Society Symposium, Denver, CO, 24-28 Oct. 1994
(Contract DE-AC04-94AL-85000)
(DE95-001525; SAND-94-1318C; CONF-941001-1) Avail: CASI HC A03/MF A01

The effect of plasma-induced-damage on the majority carrier transport properties of GaAs has been studied by monitoring changes in sheet resistance (R(sub s)) of thin conducting layers under various plasma conditions including etch conditions for refractory metal contacts. R(sub s) determined from transmission line measurements are used to evaluate plasma-induced-damage for electron cyclotron resonance (ECR) and reactive ion etch (RIE) conditions by varying the thickness of doped epitaxial layers. The authors speculate that plasma-induced-damage in the near surface region plays a major role in explaining the damage mechanism observed in this study. Very consistent trends have been observed where R(sub s) increases with increasing ECR and RIE dc-bias, increasing microwave power, and decreasing pressure, thus showing R(sub s) increases as either the ion energy or ion flux increases. The authors have also observed that R(sub s) is lower for samples exposed to the RIE than the ECR, possibly due to higher ion and electron densities generated in the ECR and higher pressures in the RIE. It has also been observed R(sub s) dependence on ECR plasma chemistry where, R(sub s) is lower in SF_6/Ar plasmas than Ar and N_2 plasmas possibly related to interactions of F or S atoms with the GaAs surface. Moderate anneal temperatures (200 to 500 C) have shown significant R(sub s) recovery. DOE

SELENOPHENE TRANSITION METAL COMPLEXES Ph.D. Thesis
C. J. White 27 Jul. 1994 134 p
(Contract W-7405-eng-82)
(DE95-001675; IS-T-1699) Avail: CASI HC A07/MF A02

This research shows that selenophene transition metal complexes have a chemistry that is similar to their thiophene analogs. Selenophene coordination has been demonstrated and confirmed by molecular structure in both the (eta)(sup 5)- and the (eta)(sup 1)(Se)-coordination modes. The reaction chemistry of selenophene complexes closely resembles that of the analogous thiophene complexes. One major difference, however, is that selenophene is a better donor ligand than thiophene making the selenophene complexes more stable than the corresponding thiophene complexes. The Se(77) NMR chemical shift values for selenophene complexes fall within distinct regions primarily depending on the coordination mode of the selenophene ligand. In the final paper, the C-H bond activation of (eta)(sup 1)(S)-bound thiophenes, (eta)(sup 1)(S)-benzothiophene and (eta)(sup 1)(Se)-bound selenophenes has been demonstrated. The deprotonation and rearrangement of the (eta)(sup 1)(E)-bound ligand to the carbon bound L-yl complex readily occurs in the presence of base. Reprotonation with a strong acid gives a carbene complex that is unreactive towards nucleophilic attack at the carbene carbon and is stable towards exposure to air. The molecular structure of (Cp(NO)(PPh(sub 3))Re(2-benzothioenylcarbene))O(sub 3)SCF(sub 3) was determined and contains a Re-C bond with substantial double bond character. Methyl substitution for the thienylcarbene or selenylcarbene gives a carbene that rearranges thermally to give back the (eta)(sup 1)(E)-bound complex. Based on these model reactions, a new mechanism for the H/D exchange of thiophene over the hydrodesulfurization catalyst has been proposed. DOE

ELECTRONIC STRUCTURE AND RELATIVE STABILITY OF ICOSAHEDRAL SUPERATOMS IN Al-TRANSITION-METAL ALLOYS
X. G. Gong and V. Kumar Oct. 1993 14 p
(DE94-628996; IC-93/352) Avail: CASI HC A03/MF A01 (US Sales Only)

The electronic structure and relative stability of icosahedral Al12TM superatoms in Al-transition-metal (TM) alloys have been studied using the density functional theory within the local spin density approximation. Our calculations predict large binding energies for superatoms with TM atom in the middle of a d-series in agreement with the occurrence of Al12W phase in these alloys and provide an insight into the understanding of the stability of Al-TM quasicrystal. OXIDATION BEHAVIOR OF ALUMINUM NANOPOWDERS
Christopher E. Aumann, Gretchen L. Skofronick, and Joe A. Martin 1994 18 p Presented at the 41st Annual American Vacuum Society Symposium, Denver, CO, 24-28 Oct. 1994 Submitted for publication Sponsored by DOD
(Contract W-7405-eng-36)
(DE95-002721; LA-UR-94-3499; CONF-941001-6) Avail: CASI HC A03/MF A01

Rutherford backscattering spectrometry, thermogravimetric analysis, and high-resolution transmission electron microscopy were used to investigate the oxidation behavior of ultrafine grain aluminum powder. Fractional change in mass of Al powder samples were obtained as a function of temperature and exposure time for samples with different particle size distributions. Activation energy for oxidation is found to depend on average Al particle size and to be much smaller than that known for flat Al samples. DOE

THE DEVELOPMENT OF A SUPER-ALPHA2 TITANIUM ALUMINIDE ALLOY CONSOLIDATED BY RAPID OMNIDIRECTIONAL COMPACTION Final Report
Wego Wang and Martin G. Wells Mar. 1994 46 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A279254; ARL-TR-341) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Six super-alpha 2 titanium aluminide 'pancakes' were produced by rapid omnidirectional compaction of prealloyed Ti-25Al-1ONb-3V-1Mo (at%) powder. The beta-transus temperature was found to be about 1,090 C (1,990 F). The alloy was heat-treated with four different schedules to develop various structure combinations of alpha(sub 2) and beta, and followed by a series of microstructural analyses and mechanical property determinations. The highest ultimate tensile and yield strengths attained at room temperatures were 1,174.9 and 977.7 MPa (170.4 and 141.8 ksi), respectively. However, the elongation was less than 2%. The alloy also showed good stress rupture resistance. It was observed that, under otherwise similar conditions, ductility increased with the aspect ratio of the alpha(sub 2) phase but the tensile strength is inversely related to the aspect ratio. During the tensile and stress rupture tests, multiple transverse cracks nucleated in the longitudinal direction on the specimen surface and within the specimen simultaneously. DTIC

PLASMA ARC MELTING OF A 80 WEIGHT PERCENT TANTALUM -20 WEIGHT PERCENT TITANIUM ALLOY
P. S. Dunn and R. A. Patterson 1994 13 p Presented at the 1994 International Conference on Tungsten and Refractory Metals, McLean, VA, 17-19 Oct. 1994
(Contract W-7405-eng-36)
(DE95-000846; LA-UR-94-3283; CONF-9410213-2) Avail: CASI HC A03/MF A01

An alloy of 80wt% tantalum-20wt% titanium is being considered for use in an oxidizing and highly corrosive liquid metal application. The high melting point of the alloy, 2400 C, and other physical properties narrowed the possible melting techniques. Previous melting experience with these materials by electron beam resulted in extensive vaporization of the titanium during the melt and poor chemical homogeneity. A technique has been developed using plasma arc melting to melt refractory alloys with very dissimilar densities and vapor pressures. The 80Ta--20Ti alloy falls into this category with the density of tantalum 16.5 g/cc and that of titanium 4.5 g/cc. The melting of these materials is further complicated by the high melting point of tantalum (3020 C) and the relatively low boiling point of titanium (3287 C). The plasma arc melting technique described results in good chemical homogeneity with ingot size quantities of material. DOE

(Contract DE-FC02-93ER-54186)
(DE95-001818; PFC/RR-94-2; DOE/ER-54186/T3) Avail: CASI HC A05/MF A01

This handbook is a compilation of all available properties of Incoloy alloy 908 as of March, 1994. Data included in this paper cover mechanical, elastic, thermal and magnetic characteristics. The mechanical properties include tensile, fracture toughness, fatigue, and stress-rupture for both the base metal and related weld filler metals. Elastic properties listed are Young's, shear and bulk moduli and Poisson's ratio. Thermal expansion, thermal conductivity and specific heat and magnetization are also reported. Data presented are summarized in the main body and presented in detail in the supplements. Areas of ongoing research are briefly described, and topics for future research are suggested. The data have been compiled to assist in the design of large-scale superconducting magnets for fusion reactors. DOE

SPECTROSCOPIC ASSESSMENT OF THE RELIABILITY OF METAL/METAL OXIDE INTERFACES Final Report, Oct. 1990 - Sep. 1991
Joseph Chaiken Oct. 1994 47 p
(Contract F30602-88-D-0028)
(AD-A286131; RL-TR-94-189) Avail: CASI HC A03/MF A01

There is considerable interest in understanding the source of the electromigration resistance of the well-known interconnect material, titanium tungsten (Ti:W). Measures of electromigration can be obtained with respect to a variety of parameters/physical properties. The variation of some parameters over time can presumably be associated with the increase in the probability of an electromigration related interconnect failure. In the simplest analysis, we immediately note that any metal in contact with the atmosphere oxidizes. Furthermore, the process is accelerated by increasing the temperature as is the rate of electromigration related failures. Therefore, a rational basis exists to suspect that oxidation related chemistry can be related to electromigration related failure processes. This study probes the oxidation chemistry in this alloy on native oxide coated silicon. We report physical and chemical measurements on the interface between a ceramic and metal phase. DTIC

A NEW METALLOGRAPHIC PROCEDURE FOR EDGE RETENTION OF ENCLOSED SURFACES
O. M. Katz 1994 10 p Presented at the 27th Annual International Metallographic Society Meeting, Montreal, Quebec, 24-27 Jul. 1994
(Contract DE-AC11-93PN-38195)
(DE94-017549; WAPD-T-3033; CONF-940793-3) Avail: CASI HC A02/MF A01

Utilization of a low melting point, metallic alloy that expands on solidification has provided a reproducible means of preserving edges and accurately measuring deposits on surfaces mounted for metallographic study. In normal laboratory practice the electrically conducting mounting material generates no hazardous waste, needs no special equipment to prepare and is available commercially at a relatively reasonable price. Previous standard edge preservation techniques were found to be 90% inefficient from a time utilization view compared with the new procedure. This new mounting procedure has greatly improved the quality and efficiency of microstructural studies of all materials, especially those on the inside diameters of heat exchanger components. These studies have included reaction products, shallow creep cracks and deposits on tubing, for which the procedure has proved indispensable. DOE

LOWER ACTIVE METALS LOADING FOR HYDROTREATING CATALYSTS
S. E. Lott, T. J. Gardner, L. I. McLaughlin, and J. B. Oelfke 1994 9 p Presented at the US/Japan Meeting on Coal Energy Research, Albuquerque, NM, 26-30 Sep. 1994
(Contract DE-AC04-94AL-85000)
(DE94-018907; SAND-94-2222C; CONF-9409207-1) Avail: CASI HC A02/MF A01

Hydrous metal oxides (HMO's) are chemically synthesized materials which contain a homogeneous distribution of ion exchangeable alkali cations that provide charge compensation to the metal-oxygen framework. Both the presence of these alkali cations and the resulting high cation exchange capacities (4-5 meq/g) clearly set these HMO materials apart from conventional precipitated hydrous oxides. For catalyst applications, the HMO material serves as an ion exchangeable support which facilitates the uniform incorporation of catalyst precursor species. Following catalyst precursor incorporation, an activation step is required to convert the catalyst precursor to the desired active phase. Considerable process development activities at Sandia National Laboratories related to HMO materials have resulted in bulk silica-doped hydrous titanium oxide (HTO:Si)-supported NiMo catalysts that are more active in model compound reactions than commercial NiMo catalysts. These reactions, e.g. pyrene hydrogenation, simulate direct coal liquefaction. However, extension of this process to produce NiMo/HTO:Si catalyst coatings on commercial supports is of interest for liquefaction applications since overall catalyst cost can be reduced and bulk HTO:Si mechanical limitations can be circumvented. In the present effort, NiMo/HTO:Si has been evaluated for hydrodesulfurization (HDS) and hydrodenitrogenation (HDN) of coal derived liquids. NiMo/HTO:Si catalysts have been evaluated in both bulk (unsupported) form and a supported form on commercial alumina extrudates. DOE

IRRADIATION CREEP IN STRUCTURAL MATERIALS AT ITER OPERATING CONDITIONS
M. L. Grossbeck 1994 8 p Presented at the Materials Issues for Severe Environments Meeting, San Diego, CA, 23-25 Jun. 1993
(Contract DE-AC05-84OR-21400)
(DE94-018946; CONF-9306367-1) Avail: CASI HC A02/MF A01

Irradiation creep is plastic deformation of a material under the influence of irradiation and stress. Below the regime of thermal creep, there remains a deformation mechanism under irradiation that is weakly temperature dependent and clearly different from thermal creep. This is irradiation creep. Both stress and irradiation are required for irradiation creep. Irradiation creep studies for applications in the past focused mostly on liquid metal fast breeder reactors where temperatures are usually above 400 C. Fusion reactors, especially nearterm devices such as the ITER will have components operating at temperatures as low as 100 C exposed to high neutron fluxes. Theories of irradiation creep based on steady-state point defect concentrations do not predict significant irradiation creep deformation at these temperatures; however, data from research reactors show that irradiation creep strains at 60 C are as high or higher than at temperatures above 300 C for austenitic stainless steels. Irradiation creep of nickel has also been observed at cryogenic temperatures. DOE

ATOM PROBE FIELD ION MICROSCOPY OF TYPE 308 CRE STAINLESS STEEL WELDS
S. S. Babu (Pennsylvania State Univ., University Park, PA.), S. A. David, J. M. Vitek, and M. K. Miller 1994 15 p Presented at the International Field Emission Symposium, Rouen, France, 15-17 Jul. 1994
(Contract DE-AC05-84OR-21400)
(DE94-019162; CONF-9407132-1) Avail: CASI HC A03/MF A01

Additions of controlled residual elements (CRE) such as titanium, boron and phosphorus, to the commercial 308 type stainless steel welds have been found to improve the creep-rupture properties. In both conventional and CRE-type stainless steel welds, during high temperature service, various microstructural changes take place such as the formation of M23C6 carbide networks along austenite(gamma)-ferrite (delta) interface, the formation of sigma phase, and the dissolution of ferrite. Boron-containing CRE welds exhibit similar microstructural evolution as that of conventional types 308 stainless steel welds. As boron may segregate to ferrite-austenite interface and thereby modify the austenite-M23C6 carbide interface, the distribution of boron was measured with an atom probe field ion microscope. Atom probe analysis revealed significant boron and carbon enrichments along the ferrite-austenite boundary in the as-welded state. The ratio of carbon to boron concentration at the interface was found to be approximately 4. DOE

CORROSION BEHAVIOR OF LANDING GEAR STEELS
Eun U. Lee 29 Oct. 1993 24 p
(AD-A285862; NAWCADWAR-94001-60) Avail: CASI HC A03/MF A01

A study was conducted on the corrosion behavior of an AerMet 100 steel and a 300M steel. This study included investigations of stress corrosion cracking (SCC), immersion corrosion, salt spray corrosion, and humidity corrosion of both steels. For the SCC investigation, double cantilever beam (DCB) specimens were employed, and for the immersion, salt spray, and humidity corrosion investigations, sheet specimens were used. The SCC rate is less and the threshold stress intensity for stress corrosion (K(sub ISCC)) is greater in the AerMet 100 steel (33 ksi*in(exp 1/2)) than in the 300M steel (19 ksi*in(exp 1/2)), indicating better SCC resistance of the AerMet 100 steel. In the AerMet 100 steel, the stress corrosion crack grows along an intergranular and transgranular path in the direction of forging deformation. The immersion corrosion and salt spray corrosion rates of the AerMet 100 steel is 33 - 40% and 13 - 20% of those for the 300M steel, respectively. Evidence of humidity corrosion is not detectable in the AerMet 100 steel within the employed test period 110 days, whereas it is substantial (2.0413 mpy or 0.0447 mdd) in the 300M steel. The overall results indicate that the AerMet 100 steel is superior to the 300M steel with respect to the corrosion resistance as well as the mechanical properties. DTIC

CHARACTERIZATION OF A TEXTURE GRADIENT IN TANTALUM PLATE

S. I. Wright and G. T. Gray, III 1994 7 p Presented at the 3d International Symposium on Structural and Functional Gradient Materials, Lausanne, Switzerland, 10-12 Oct. 1994
(Contract W-7405-eng-36)
(DE95-002704; LA-UR-94-3413; CONF-9410244-1) Avail: CASI HC A02/MF A01

Clark et al. have shown that significant texture gradients can be produced in rolled tantalum plate and that the strength of the gradient is dependent on the processing path. Texture gradients are often ignored because they are time consuming to characterize and add significant complexity to materials modeling. The variation in texture through the thickness of rolled materials is most commonly measured by sectioning samples to different depths through the thickness of the plate and then measuring the texture from these section planes by X-ray diffraction. A new technique based on automatic indexing of electron backscatter diffraction patterns in the scanning electron microscope enables spatially specific orientations to be measured in a practical manner. This technique allows spatial variations in texture to be measured directly enabling gradients in texture to be investigated in more detail than previously possible. This data can be used directly in coupled finite-element/ polycrystal-plasticity models to simulate the effects of variations in texture on the plastic behavior of polycrystals. This work examines the variation in texture through the thickness of a tantalum plate and its resultant effect on the compressive deformation of samples prepared from the plate. The characterization of the texture gradient using the automatic point-by-point measurement technique mentioned above is described in detail. The effect of the gradient on the plastic response of through-thickness compression tests is also discussed. DOE

STUDIES OF THE MICROWAVE RESISTIVITY OF KAPPA-(BEDT-TTF)2Cu(N(CN)2)Cl

M. Dressel (California Univ., Los Angeles, CA.), G. Gruener (California Univ., Los Angeles, CA.), K. D. Carlson, H. H. Wang, and J. M. Williams 1994 3 p Presented at the International Conference on Science and Technology of Synthetic Metals, Seoul, Republic of Korea, 24-29 Jul. 1994 Submitted for publication Sponsored in cooperation with Alexander von Humbolt Foundation
(Contract W-31-109-eng-38)
(DE95-002980; ANL/CHM/CP-84363; CONF-9407117-4) Avail: CASI HC A01/MF A01

The authors have performed temperature dependent measurements of the surface impedance of kappa-(BEDT-TTF)2Cu(N(CN)2)Cl in both directions, parallel and perpendicular to the highly conducting planes. In both orientations the microwave resistivity basically follows the dc behavior for T greater tha n 15 K: the crystal undergoes a broad metal-insulator transition at around 50 K. While there are no indications of superconductivity at ambient pressure found in the dc resistivity and by ac susceptibility, the microwave resistivity clearly drops at 13 K and again at 5 K, indicating two superconducting phases. When pressure is applied by embedding it in grease, only the well known superconducting phase transition at (Tc) = 13 K remains. DOE

EFFECT OF ANNEALING TEMPERATURE ON THE TEXTURE OF ROLLED TANTALUM AND TANTALUM-10 WT % TUNGSTEN

Stuart I. Wright, Sherri R. Bingert, and Melissa D. Johnson 1994 8 p Presented at the 1994 International Conference on Tungsten and Refractory Metals, McLean, VA, 17-19 Oct. 1994
(Contract W-7405-eng-36)
(DE95-002702; LA-UR-94-3431; CONF-9410213-3) Avail: CASI HC A02/MF A01

The effect of annealing temperature on crystallographic texture was investigated on straight- and cross-rolled Ta and cross-rolled Ta-10wt%W sheets. Textures were measured on coupons cut from rolled sheets and annealed for one hour at 800 to 1550 C. In particular the effect of annealing temperature on volume fraction of grains having (111) and (100) crystal directions nearly aligned with the plate normal was investigated. In the pure tantalum sheets, increased annealing temperature lead to increased fractions of the (111) component. The same was true for the Ta-10wt%W but much higher temperatures were required to change the texture from a (100) type texture to a more (111) type texture. In addition, the influence of the annealing temperature on the sharpness of the texture; on the surface to centerline texture gradient; and on the in-plane symmetry of the texture was investigated. DOE

BULK AND DEFECT PROPERTIES OF ORDERED INTERMETALLICS

C. L. Fu and M. H. Yoo 1993 10 p Presented at the Fall Meeting of the Minerals, Metals and Materials Society: Physical Metallurgy and Materials, Pittsburgh, PA, 17-21 Oct. 1993
(Contract DE-AC05-84OR-21400)
(DE94-017706; CONF-931009-29) Avail: CASI HC A02/MF A01

First-principles calculations based on the local-density-functional theory have been used to investigate the factors governing strength of ordered intermetallic alloys. Unlike Ni3Al, calculated elastic constants and shear fault energies indicate anomalous yield strength behavior is not likely to occur in Ni3Si. This suggests the inadequacy of cross-slip-pinning model to explain the strength anomaly in the L1(sub 2) structure. For strongly ordered NiAl, the defect structure is dominated by two types of defects - monovacancies on the Ni sites and substitutional antisite defects on the Al sites. By contrast, for Ni3Al, absence of structural vacancies and deviations from stoichiometry are accommodated by substitutional antisite defects on both sublattices. Intrinsic strengthening mechanisms in TiAl are discussed in terms of calculated elastic constants and shear fault energies. Because of reduced fault energies at the gamma/(alpha 2) interface, slip and twinning contribute significantly to high shear deformation of the lamellar structure. DOE

PROCESSING OF INTERMETALLIC MATERIALS BY REACTION SYNTHESIS
C. T. Liu 1994 9 p Presented at the Workshop on Solidification and Processing, Boston, MA, 18-22 Jul. 1994
(Contract DE-AC05-84OR-21400)
(DE94-017710; CONF-9407122-1) Avail: CASI HC A02/MF A01

This paper provides a brief summary of recent work on reaction synthesis of Ni3Al/NiAl powder compacts at Oak Ridge National Laboratory. Both reaction extent and densification process depend strongly on heat accumulation and heat transfer, which can be effectively controlled by exerting compressive stresses, as well as aluminum concentration and compact thickness. Three distinct stages are observed, corresponding to (1) initial reaction to (no formation of transient liquid phases); (2) partial reaction (occurrence of self-propagating combustion reaction); and (3) full reaction (combustion reaction + conversion reaction). A nearly full density product was obtained in both the fully reacted zone and partially reacted zones during reaction synthesis under compressive stresses. DOE

TENSILE AND IMPACT PROPERTIES OF IRON-ALUMINUM ALLOYS
D. J. Alexander and V. K. Sikka 1993 16 p Presented at the Fall Meeting of the Minerals, Metals and Materials Society: Physical Metallurgy and Materials, Pittsburgh, PA, 17-21 Oct. 1993
(Contract DE-AC05-84OR-21400)
(DE94-017750; CONF-931009-28) Avail: CASI HC A03/MF A01

Tensile and impact tests have been conducted on specimens from a series of five heats of iron-aluminum alloys. These results have been compared to data for the iron aluminide alloy FA-129. The transition temperatures of all of the Fe3Al-based alloys were similar, but the simple ternary alloy had a much higher upper-shelf energy. The reduced aluminum alloys (based on Fe-8Al (wt %)) had lower transition temperatures and higher upper-shelf energy levels than the Fe3Al-type alloys. The reduced aluminum alloy with yttrium showed excellent tensile properties, with a room temperature total elongation of 40%, and a very high upper-shelf energy level. Despite the high tensile ductility at room temperature, the transition temperature of the yttrium-containing alloy was still about 150 C, compared to approximately 300 C for FA-129. In general, the microstructures were coarse and anisotropic. The fracture processes were dominated by second-phase particles. DOE

NEW THERMODYNAMIC DESCRIPTION OF THE Cu-Zr SYSTEM
K. Zeng and M. Haemaelaeinen 1994 36 p
(PB95-127189; TKK-V-B88) Avail: CASI HC A03/MF A01

An optimized set of thermodynamic functions for the Cu-Zr system has been obtained by the least squares method from phase diagram and thermodynamic data available in the literature. The excess free energies of the solution phases, liquid and three terminal solid solutions, were described by the Redlich-Kister formula. All the intermediate compounds were treated as stoichiometric phases. The calculated phase diagram, as well as the thermodynamic properties vs. compositions, agree well with the experimental values. The reliability of the optimized parameters have been examined using mu-T plots. NTIS

AN UPDATE OF CORROSION INHIBITORS FOR MILD STEEL EXPOSED TO 32-0-0 UAN SOLUTION
D. T. Nguyen, D. E. Nichols, and E. J. Lohry (Nutra-Flo Co., Sioux City, IA.) 1994 21 p Presented at the 206th American Chemical Society (ACS) National Meeting, Chicago, IL, 22-27 Aug. 1993
(DE95-001715; CONF-930802-22; Z-337) Avail: CASI HC A03/MF A01

This is a continuation of corrosion studies on the effectiveness of commercial and newly-developed corrosion inhibitors for use with mild steel exposed to urea-ammonium nitrate (UAN) solution. This paper provides updated information on five newly-developed corrosion inhibitors. Tests were conducted with mild steel exposed to 32-0-0 UAN solution containing each corrosion inhibitor at ambient temperature and under static conditions. Real-time corrosion of the test specimens was monitored using AC impedance techniques. Corrosion performance of the inhibitors was evaluated based on comparison of the corrosion rate of specimens exposed to 32-0-0 UAN solution with and without a corrosion inhibitor. DOE

FRACTURE BEHAVIOR OF LAMINATED DISCONTINUOUSLY REINFORCED ALUMINUM MATERIAL
T. M. Osman (Case Western Reserve Univ., Cleveland, OH.) and J. J. Lewandowski (Case Western Reserve Univ., Cleveland, OH.) May 1994 10 p Presented at the 4th International Conference of Aluminum Alloys, Atlanta, GA, 11-16 Sep. 1994
(Contract W-7405-eng-48)
(DE94-017307; UCRL-JC-117162; CONF-9409179-3) Avail: CASI HC A02/MF A01

Laminated metallic composites are being developed for applications which require high specific stiffness and fracture resistance. Recent work with laminated discontinuously reinforced aluminum (DRA) materials has demonstrated the potential for marked improvements in stable crack growth resistance via extrinsic toughening. The purpose of this work is to compare the fracture mechanisms and fracture resistance of laminated DRA materials to unlaminated DRA materials. In particular, the production of extensive stable crack growth and the associated improvement in damage tolerance in DRA laminates is documented. DOE

REACTIVE COMPATIBILIZATION OF POLYMER BLENDS Final Report, 1 Jul. 1991 - 30 Jun. 1994
D. R. Paul 1 Aug. 1994 18 p
(Contract DAAL03-91-G-0128)
(AD-A284836) Avail: CASI HC A03/MF A01

This research has examined the use of functionalized polymers that react at the interfaces in polymer blends to form block or graft copolymers during melt processing. These grafts act as 'compatibilizers' that strengthen the interface and provide a powerful means of controlling blend phase morphology. Consequently, this approach provides an effective means of controlling the properties of multiphase polymeric materials. Most of the work involved the use of various polyamides as one component in the blend. The other component was a reactive elastomer, an acrylonitrile-butadiene-styrene (ABS) material, a core-shell impact modifier, or polypropylene. The end group configuration of the polyamide was shown to be an important consideration in morphology development. Functionalized additives are most efficient when both physical and chemical interactions are optimized. A variety of approaches for producing super-tough polyamide blends with low ductile-brittle transition temperatures are described. Cavitation of the rubber phase was shown to be an important part of the roughening mechanism in certain cases. DTIC

A TEST OF THE ARRHENIUS EXTRAPOLATION ASSUMPTION FOR A NITRILE RUBBER
K. T. Gillen, J. Wise, and R. L. Clough 1994 4 p Presented at the 19th Department of Energy Conference on Compatibility, Aging and Service Life, Los Alamos, NM, 28-30 Sep. 1994
(Contract DE-AC04-94AL-85000)
(DE94-017337; SAND-94-2035C; CONF-9409181-2) Avail: CASI HC A01/MF A01

The Arrhenius relation predicts a linear relation between log of time to property change and inverse absolute temperature, with the Arrhenius activation energy E(sub a) given from the slope. For a nitrile rubber, Arrhenius behavior is observed for elongation versus air-oven aging temperature, with a E(sub a) of 22 kcal/mol. Confidence in extrapolation to low temperatures can be increased by measuring oxygen consumption. From 95 to 52 C, the E(sub a) for oxygen consumption is identical to that for elongation; however, below 52 C, the E(sub a) for oxygen consumption drops slightly to 18 kcal/mol, indicating that the extrapolation assumption probably overestimates the tensile property lifetime by a factor of about two at 23 C. TECHNICAL SUMMARY FOR 1993 FALL MRS SYMPOSIUM O, COMPLEX FLUIDS
19 Aug. 1994 4 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-94-1-0129)
(AD-A283722) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The fall 1993 Symposium 'O', Complex Fluids, consisted of 24 invited talks, 60 contributed papers, and over 40 contributed posters, covering the static and dynamic properties of complex fluids in bulk and at interfaces. The subject matter of 'complex fluids' comprises a wide variety of materials outside conventional condensed matter physics, including colloidal suspensions, gels, polymer melts or solutions, and surfactant-containing phases. These diverse systems have in common a number of features, including self-assembly. Many complex fluids contain mesoscopic structures that assemble spontaneously from constituent molecules, which are often specially designed to result in a particular self-assembled structure. Amphiphilic or surfactant molecules, with polar and non-polar regions on the same molecule, aggregate into a huge variety of structures, including micelles, monolayers, and bilayers. Block copolymers, consisting of chemically dissimilar polymer chains covalently joined together, behave in analogous ways. From the mesoscopic self-assembled building blocks, a wide variety of phases are formed, including many phases with crystalline or liquid crysalline order. Complex fluids also have a complex rheology and a broad application in common. DTIC

RECOGNITION OF SUBSURFACE DEFECTS IN MACHINED CERAMICS BY APPLICATION OF NEURAL NETWORKS TO LASER SCATTER PATTERNS
Michael C. Stinson (University of Central Michigan, Mount Pleasant, MI.), Owen W. Lee (California Univ., Los Angeles, CA.), J. Scott Steckenrider, and William A. Ellingson 1994 4 p Presented at the 18th Annual Conference on Composites and Advanced Ceramics, Cocoa Beach, FL, 9-14 Jan. 1994
(Contract W-31-109-eng-38)
(DE94-018373; ANL/ET/CP-80540; CONF-940135-11) Avail: CASI HC A01/MF A01

Laser scatter has shown promise as a method to characterize damage microstructural variations as well as a method to characterize surfaces in optical translucent ceramics. Because large volumes of data need to be handled (and sorted) quickly, automated pattern recognition methods using neural networks have been implemented to recognize differences in patterns. A He-Ne laser (lambda)=0.632(mu) has been used to obtain scatter patterns from hot pressed Si3N4 with various microstructur al variations. By use of a backpropagation neural network running on an IBM PC clone 486/33 machine, a correlation was established between subsurface microstructure and position in Si3N4 b all bearings. The data were confirmed by destructive analysis. DOE

PROPERTIES OF WHISKER-REINFORCED CERAMICS
P. F. Becher, C. H. Hsueh, H. T. Lin, K. B. Alexander, T. N. Tiegs, W. H. Warwick, and S. B. Waters 1994 25 p Presented at the 96th Annual Meeting of the American Ceramic Society, Indianapolis, IN, 24-28 Apr. 1994
(Contract DE-AC05-84OR-21400)
(DE94-017759; CONF-940416-24) Avail: CASI HC A03/MF A01

The paper summarizes studies of SiC whisker-reinforced alumina composites, their properties and the influence of composition and microstructure. Both steady-state toughness and R-curve response increase with whisker content and diameter. Room temperature flexure strength of aluminas with different grain sizes also increases with whisker content. Resistance to slow crack growth under both monotonic and cyclic loading is improved by whisker reinforcement compared to alumina and other ceramics. The thermal conductivity and electrical resistivity exhibit a substantial increase and decrease, respectively, with whisker loadings above 10 vol %. Thermal expansion coefficients decrease in a systematic fashion with increase in whisker content. However, the expansion coefficients are greater parallel to hot pressing axis compared to perpendicular direction owing to internal stresses and preferred orientation of whiskers. The changes in mechanical and thermal properties due to SiC whisker additions result in substantial improvement in thermal shock resistance for samples of various sizes. At elevated temperatures, tests in air show that improvements in strength and resistance to strength degradation are associated with SiC whisker reinforcement. The limiting factors in elevated temperature mechanical response of the composite at 1200C and above are related to surface oxidation-reaction processes and creep. On the other hand, the creep resistance of the composite is far greater than alumina with a similar fine grain size at temperatures less than or equal to 1200C. Furthermore by increasing the grain size of the alumina matrix, creep resistance of the composite can be increased. In essence, SiC whisker reinforced alumina composites provide an example of a system whose properties can be tailored through control of microstructure and composition. DOE

SOL-GEL-DERIVED SILICA FILMS WITH TAILORED MICROSTRUCTURES FOR APPLICATIONS REQUIRING ORGANIC DYES
M. N. Logan, S. Prabakar (New Mexico Univ., Albuquerque, NM.), and C. J. Brinker 1994 7 p Presented at the Spring Meeting of the Materials Research Society, San Francisco, CA, 4-8 Apr. 1994
(Contract DE-AC04-94AL-85000)
(DE94-018886; SAND-93-4010C; CONF-940411-52) Avail: CASI HC A02/MF A01

A three-step sol-gel process was developed to prepare organic dye-doped thin films with tailored porosity for applications in chemical sensing and optoelectronics. Varying the acid- and base-catalyzed hydrolysis steps of sols prepared from tetraethoxysilane with identical final H2O/Si ratios, dilution factors and pH resulted in considerably different distributions of the silicate polymers in the sol (determined by Si-29 NMR) and considerably different structures for the polymer clusters (determined by SAXS). During film formation these kinetic effects cause differences in the packing and collapse of the silicate network, leading to thin films with different refractive indices and volume fraction porosities. Under conditions where small pore-plugging species were avoided, the porosities of as-deposited films could be varied by aging the sol prior to film deposition. This strategy, which relies on the growth and aggregation of fractal polymeric clusters, is compatible with the low temperature and near neutral pH requirements of organic dyes. DOE

ACCELERATED SCREENING METHODS FOR DETERMINING CHEMICAL AND THERMAL STABILITY OF REFRIGERANT-LUBRICANT MIXTURES. PART 2: EXPERIMENTAL COMPARISONS AND VERIFICATION OF METHODS
R. Kauffman (Dayton Univ., OH.) Jul. 1994 52 p
(Contract DE-FG02-91CE-23810)
(DE95-000743; DOE/CE-23810/38C-Pt-2) Avail: CASI HC A04/MF A01

The research reported herein continued to concentrate on in situ conductivity measurements for development into an accelerated screening method for determining the chemical and thermal stabilities of refrigerant/lubricant mixtures. The work reported herein was performed in two phases. In the first phase, sealed tubes were prepared with steel catalysts and mixtures of CFC-12, HCFC-22, HFC-134a, and HFC-32/HFC-134a (zeotrope 30:70) refrigerants with oils as described in ANSI/ASHRAE Method 97-1989. In the second phase of work, modified sealed tubes, with and without steel catalysts present, were used to perform in situ conductivity measurements on mixtures of CFC-12 refrigerant with oils. The isothermal in situ conductivity measurements were compared with conventional tests, e.g., color measurements, gas chromatography, and trace metals to evaluate the capabilities of in situ conductivity for determining the chemical and thermal stabilities of refrigerant/lubricant mixtures. Other sets of tests were performed using ramped temperature conditions from 175 C 347 F to 205 C 401 F to evaluate the capabilities of in situ conductivity for detecting the onset of rapid degradation in CFC-12, HCFC-22 and HFC-134a refrigerant mixtures with naphthenic oil aged with and without steel catalysts present. THIANTHRENE CONTAINING POLYIMIDES WITH MONOMER FORMATION VIA NUCLEOPHILIC AROMATIC SUBSTITUTION
Masaru Yoneyama, Randy A. Johnson, and Lon J. Mathias 7 Nov. 1994 29 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-89-J-1225)
(AD-A286313; TR-75) Avail: CASI HC A03

Thianthrene-2,3,7,8 - tetracarboxylic dianhydride was synthesized via nucleophilic aromatic substitution of N-phenyl-4,5-dichlorophthalimide with thiobenzamide, thioacetamide, and sodium sulfide. This monomer was then polymerized with aromatic diamines by the conventional low temperature technique in N, N-dimethylacetamide (DMAc) to yield soluble poly(amic acid)s. Polyimides were obtained by thermal cyclization of the poly(amic acid) films. Polymers obtained formed creasable thin films and had excellent thermal stability in air and nitrogen. The bent thianthrene structure limited crystallization and chain-packing as indicated by x-ray analysis. The highly amorphous thianthrene containing polyimides were only soluble in H2SO4. DTIC

THE ELECTRONIC PROPERTIES OF POLYSILANES
R. G. Kepler and Z. G. Soos (Princeton Univ., NJ.) 1994 22 p Presented at the International Conference on Polymers for Microelectronics, Kawasaki, Japan, 14-19 Nov. 1994
(Contract DE-AC04-94AL-85000)
(DE94-006464; SAND-94-0198C; CONF-941132-1) Avail: CASI HC A03/MF A01

Results of recent studies of the electronic properties of polysilanes are reviewed. The electronic states can be described by the Hueckel model if coulomb interactions are included using the Pariser-Parr-Pople approximation. The long polymer chains appear to be divided into random length, short, ordered segments by conformational defects, with the energy of the excited states depending on the length of the segments. In isolated polymer chains energy is transferred from high-energy, short segments to longer, lower energy segments but the distance and time during which transfer take place is very limited. In solid films the excitons become highly mobile and remain mobile throughout their lifetime, even at low temperatures. Holes are quite mobile in solid films and the characteristics of transport are the same as those of charge carrier transport in molecularly doped polymer films. DOE

REACTIONS AND MICROSTRUCTURE AT CERAMIC/METAL INTERFACES
A. P. Tomsia (California Univ., Berkeley. Lawrence Berkeley Lab, CA.) and R. E. Loehman 1993 19 p Presented at the 7th International Conference on Surface Modification Technology, Nagaoka, Japan, 1-3 Nov. 1994
(Contract DE-AC04-94AL-85000)
(DE94-014287; SAND-93-1306C; CONF-941181-1) Avail: CASI HC A03/MF A01

Reactions of Ti and Zr with AlN, Al2O3 and mullite were studied. The substrates were selected to represent a simple nitride (AlN), a simple oxide Al2O3, and a complex oxide (mullite). The activities of the Ti and Zr were varied by dissolving them at 1 and 5 wt.% in the 72Ag-28Cu eutectic composition, which is otherwise unreactive with the ceramics. Reactions were studied by measuring the variation of the alloy contact angle on the ceramic with time at temperature and by determining the compositions of interfacial reaction products. The reaction products were determined by SEM-EDS, EPMA and XRD hose analysis. Contact angles were lower for Ti alloys than for those containing Zr. Reaction products were primarily the nitrides of Zr and Ti for reaction with AlN and the respective oxides for reaction with Al2O3. Complex alloy phases were found in the metal away from the ceramic-metal reaction zone. DOE

ENHANCEMENT OF CREEP RESISTANCE OF A SINTERED S3N4 CERAMIC BY MICROWAVE ANNEALING
K. C. Liu, C. O. Stevens, C. R. Brinkman, K. L. More, J. D. Kiggans, and T. N. Tiegs 1994 4 p Presented at the 5th International Symposium on Ceramic Materials and Components for Engines, Shanghai, China, 29 May - 1 Jun. 1994
(Contract DE-AC05-84OR-21400)
(DE94-017698; CONF-9405187-2) Avail: CASI HC A01/MF A01

Creep behavior was investigated for a sintered Si3N4 ceramic following microwave annealing at 1400 and 1500C for 20 h. Results of creep tests at 1200C showed that microwave annealing can enhance the creep resistance in terms of lowering creep rate and, hence, extending creep rupture life, but the 1400C annealing was most effective. X-ray diffraction analyses showed that the crystalline second phase was transformed as a result of microwave annealing from single phase Y10Al2Si3O18N4 to several different phases. The situation was further complicated by evolution of additional phases during high temperature creep experiments. DOE

MICROWAVE SINTERING OF ZrO2-12 MOL% CeO2
Mark A. Janney, Mitchell L. Jackson, and Hal D. Kimrey 1993 8 p Presented at the 95th Annual Meeting of the American Ceramic Society, Cincinnati, OH, 18-22 Apr. 1993
(Contract DE-AC05-84OR-21400)
(DE94-018709; CONF-930438-32) Avail: CASI HC A02/MF A01

Sintering of ZrO2-12 mol% CeO2 was accelerated by microwave processing at 2.45 GHz as compared with conventional firing. However, the size of the 'microwave effect' was significantly smaller than that which was previously observed for microwave sintering of ZrO2-8 mol% Y2O3. The difference in the effect that the microwave field had on the two zirconia systems is interpreted in terms of their ionic conductivities. DOE

THE PREPARATION OF ALL PARA-POLYPHENYLS WITH INCREASED SOLUBILITY AND ENHANCED THIRD ORDER NLO ACTIVITY Final Report
Marilyn R. Unroe and Bruce A. Reinhardt Jun. 1994 37 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AF Proj. 2303)
(AD-A284301; WL-TR-94-4070) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

A series of all para-polyphenyenes up to heptaphenyl were prepared with solubilizing n-decyloxy pendants. The n-alkoxy pendants allow solubility in tetrahydrofuran for evaluation by femtosecond degenerate four-wave mixing. The physical, chemical, and electro-optical measurements are summarized. The oligomers corresponding to monomer and trimer have increased second hyperpolarizability due to purely extended pi-conjugation effects. However, the pentamer and heptamer evaluations indicated large increases in hyperpolarizability which were not solely attributable to conjugation increases. Furthermore, two-photon resonance enhancement was confirmed in the heptamer by an upconverted blue emission of the heptamer solution at 602nm. Two photon resonance was suspected in the pentamer because of less intense blue emission. DTIC

EFFECTS OF AMBIENT CONDITIONS ON THE ADHESION OF CUBIC BORON NITRIDE FILMS ON SILICON SUBSTRATES
G. F. Cardinale (California Univ., Davis, CA.), D. G. Howitt (California Univ., Davis, CA.), P. B. Mirkarimi, K. F. McCarty, E. J. Klaus, and D. L. Medlin 1994 14 p Presented at the International Conference on Metallurgical Coatings and Thin Films, San Diego, CA, 25-29 Apr. 1994
(Contract DE-AC04-76DP-00789)
(DE94-016779; SAND-94-8620C; CONF-940440-4) Avail: CASI HC A03/MF A01

Effect of environmental conditions on cubic boron nitride (cBN) film adhesion to silicon substrates was studied. cBN films were deposited onto (100)-oriented silicon substrates by ion-assisted pulsed laser deposition. Irradiating ions were mixtures of nitrogen with argon, krypton, and xenon. Under room-ambient conditions, the films delaminated in the following time order: N/Xe, N/Kr, and N/Ar. cBN films deposited using N/Xe ion-assisted deposition were exposed to four environmental conditions for several weeks: a 1-mTorr vacuum, high humidity, dry oxygen, and dry nitrogen. Films exposed to the humid environment delaminated whereas those stored under vacuum or in dry gases did not. Films stored in dry nitrogen were removed after nearly two weeks and placed in the high-humidity chamber; these films subsequently delaminated within 14 hours. DOE

OVERVIEW ON SUPERPLASTICITY RESEARCH ON SMALL-GRAINED MATERIALS
Oleg D. Sherby (Stanford Univ., CA.), T. G. Nieh, and J. Wadsworth Jul. 1994 12 p Presented at the International Conference on Superplasticity in Advanced Materials (ICSAM), Moscow, Russia, 24-26 May 1994
(Contract W-7405-eng-48)
(DE94-016550; UCRL-JC-117600; CONF-9405193-2) Avail: CASI HC A03/MF A01

Superplasticity is generally associated with fine grains, grain boundary sliding, and high tensile ductility at elevated temperature. This paper reviews some of the recent important findings in fine-grained superplasticity, including the areas of superplastic ceramics and bf-high-strain-rate superplasticity (HSRS). Deformation mechanism maps are shown to be powerful tools for predicting the conditions where HSRS can be expected. Ultrafine grained materials, processed economically, remain an important objective in achieving HSRS. Threshold stresses, observed in fine-grained superplastic materials, are shown to be functions of temperature and grain size but their origin, however, remains obscure. Quasi-superplastic materials, with a strain-rate-sensitivity exponent of $m = 0.33$, are shown to have high elongations, and have considerable promise for netshape isothermal forming of sheet and bulk components. The development of advanced deposition technologies is continuously evolving for the synthesis of oxide coatings used in optical applications. Recent progress is made in the use of magnetron sputtering to reactively deposit metal-oxide thin films. Sputter deposition parameters are chosen to vary the composition along the film growth direction. The key process parameter to control is the sputtering rate of the target. The shape of the composition profile directly corresponds to the preselected variation of deposition rate. By simply varying the sputtering rate using a working gas that consists of an inert-oxygen mixture, structures are synthesized with composition profiles which can be either abrupt or graded in the growth direction. The result is a compositionally modulated structure of the metal-oxide system. This procedure for composition modulated synthesis is demonstrated for metals which are highly reactive with oxygen as well as for those metals which are not. The development of this deposition methodology will facilitate the design of metal oxide films for optical applications, as in gradient-index filters for example. Results are presented for the reactive sputter deposition of metal oxide coatings in the Y-O, Mo-O, and Cu-O systems. DOE

MICROSTRUCTURAL CONTRIBUTIONS TO THE FRACTURE RESISTANCE OF SILICON NITRIDE CERAMICS
P. F. Becher, S. L. Hwang, H. T. Lin, and T. N. Tiegs 1994 12 p Presented at the International Conference on Silicon Nitride-Based Ceramics, Stuttgart, Germany, 4-6 Oct. 1993
(Contract DE-AC05-84OR-21400)
(DE94-018955; CONF-931030-1) Avail: CASI HC A03/MF A01

There is a need to understand the parameters that influence the fracture resistance and strength response in self-reinforced silicon nitride ceramics. This paper attempts to address a few of the microstructural factors that are found to influence crack wake processes and the fracture resistance response in self-reinforced silicon nitride ceramics and similar systems. THE SYNTHESIS AND CHARACTERIZATION OF NEW MESOGENIC DIACETYLENE MONOMERS AND THEIR POLYMERS Technical Report, Jun. 1993 - Jun. 1994
Paula T. Hammond and Michael F. Rubner Jun. 1994 44 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-91-J-1381)
(AD-A286188) Avail: CASI HC A03

A series of three functionalized semirigid aromatic thermotropic diacetylene liquid crystals were prepared: an aromatic diacid containing tetramethylene spacers on either side of the diacetylene group (5,7 DODBA), and aromatic diols with four and nine methylene spacers (5,7 DHDP and 10,12 DHDP). This paper addresses the design and synthesis of the monomers, their liquid crystalline behavior, and the reactivity of their diacetylene groups. 5,7 DODBA and 5,7 DHDP each exhibited smectic phases. For the 5,7 DODBA diacid, in particular, hydrogen bonding is thought to play a significant role in the mesogenic behavior and the high stability of the mesophase. The mesogenic nature of 10,12 DHDP was inconclusive, though a liquid crystalline phase may exist within a narrow temperature range. Each of the monomers was photoreactive, producing deeply colored, conjugated polydiacetylene chains via topochemical polymerization upon exposure to UV or electron beam irradiation. The degree of reactivity in the solid state was much greater for the 10,12 DHDP monomer than for the 5,7 monomers due to the added flexibility of the longer methylene spacer. On the other hand, thermally induced liquid state polymerization appeared to be much faster in 5,7 DHDP and DODBA, due perhaps to the more rigid nature of these molecules in the melt. Polymers obtained from the liquid crystalline monomers are polydiacetylenes with functionalized mesogenic side chains. The partially polymerized diacetylene of 10,12 DHDP monomer exhibited clear mesogenic melt behavior based on thermal analysis, optical microscopy, and wide angle x-ray diffraction. DTIC

THE EFFECT OF FIBER COATING THICKNESS ON THE INTERFACIAL PROPERTIES OF A CONTINUOUS FIBER CERAMIC MATRIX COMPOSITE
E. Lara-Curzio, M. K. Ferber, and R. A. Lowden 1994 15 p Presented at the 18th Annual Conference on Composites and Advanced Ceramics, Cocoa Beach, FL, 9-14 Jan. 1994
(Contract DE-AC05-84OR-21400)
(DE94-017886; CONF-940135-7) Avail: CASI HC A03/MF A01

The interfacial properties (coefficient of friction, residual clamping stress, residual axial stress, and debond stress) of a continuous fiber ceramic composite were determined by means of single-fiber push-out tests. The composite consisted of Nicalon(trademark) fibers, that had been coated prior to matrix infiltration with carbon layers ranging in thickness from 0.03 to 1.2 micrometers, and a SiC matrix. It was found that the effective interfacial frictional stress decreased as the thickness of the carbon layer increased, from 24.6 +/- 9.9 MPa for a thickness of 0.03 Jim to 5.8 +/- 1.4 MPa for a thickness of 1.25 micrometers. It was also found that both the coefficient of friction and the residual clamping stress decreased as the thickness of the carbon layer increased. These results are explained in terms of the state of residual stresses in this composite and the role of the fiber surface topography during fiber sliding. DOE

THERMO-MECHANICAL FATIGUE OF POLYMER MATRIX COMPOSITES
L. H. Strait Oct. 1994 133 p
(Contract N00039-92-C-0100)
(AD-A285931; ARL/PSU/TR-94-12) Avail: CASI HC A07/MF A02

Thermo-mechanical fatigue occurs when a component is exposed to thermal cycling under mechanical constraint and or superimposed mechanical loading. Thermo-mechanical loading is an increasingly common service condition for polymer matrix composite materials. Unfortunately, little or no information is available regarding the behavior of polymer composites subject to this loading condition. The present thesis research program was undertaken to evaluate the effects of mechanical constraint on the response of polymer matrix composites during thermal cycling. Analytical and experimental techniques were used to characterize the response of carbon fiber reinforced cyanate ester (IM6/BT3008) and bismaleimide (IM7/5240-4) composites. Cross-ply laminates were subjected to thermal cycles from 24 to 177 C in the unconstrained, fully-constrained and over-constrained conditions. Laminate response, damage mechanisms and residual compressive properties were characterized for each material and degree of constraint. Predicted ply stress distributions are significantly different for the various degrees of constraint and are highly sensitive to temperature-dependent lamina properties and laminate stress free temperature. Predictions of laminate response correlate well with experimental results. Deviations are apparent at elevated temperature which are attributed to the effects of time-dependent deformation. DTIC

THE ROLE OF HIGH PRESSURE IN THE STUDY AND APPLICATIONS OF THE FERROELECTRIC POLYMER POLYVINYLIDENE FLUORIDE AND ITS COPOLYMERS
G. A. Samara, R. A. Graham, and F. Bauer (Institut Franco-Allemand de Recherches, Saint-Louis, France.) 1994 6 p Presented at the 8th International Symposium on Electrets, Paris, France, 12 Jul. 1994
(Contract DE-AC04-94AL-85000)
(DE94-015742; SAND-94-1926C; CONF-9407105-1) Avail: CASI HC A02/MF A01

Effects of frequency, temperature and hydrostatic pressure on dielectric properties, molecular relaxations, and phase transitions of PVDF and a copolymer with 30 mol % trifluoroethylene are discussed. Pressure causes large slowing down of the beta molecular relaxations as well as large increases in the ferroelectric transition temperatures and melting points, but the magnitudes of the effects are different for the different transitions. These effects can be understood in terms of pressure-induced hindrance of the molecular motions and/or reorientations. A unique application of these polymers as time-resolved dynamic stress gauges based on PVDF studies under very high pressure shock compression is discussed. DOE

A DIRECT PROCESS FOR PREPARING SEMI-CRYSTALLINE POLYIMIDES Patent Application
Alice C. Chang, inventor (to NASA) (Lockheed Engineering and Sciences Co., Hampton, VA.) and Terry L. St.Clair, inventor (to NASA) 1 Sep. 1994 16 p
(NASA-Case-LAR-15020-1; NAS 1.71:LAR-15020-1;
US-Patent-Appl-SN-299385) Avail: CASI HC A03/MF A01

The invention is a direct process for preparing semi-crystalline polyimides. This process comprises the steps of: providing a polar aprotic solvent, adding a dianhydride and a diamine to the solvent to form a mixture, stirring the mixture at ambient temperature, and adding glacial acetic acid to the mixture to provide a ratio of polar aprotic solvent to glacial acetic acid which ranges from about 90 to 10 to about 75 to 25 by volume to form a solution. The solution was heated to a range from about 110 C to about 140 C to form a polyimide precipitate. The polyimide precipitate was recovered as a semi-crystalline polyimide powder. NASA

VACUUM HOLDING FIXTURE AND METHOD FOR FABRICATING PIEZOELECTRIC POLYMER ACOUSTIC SENSORS Patent Application
E. Thomas Hall, Jr., inventor (to NASA) and Timothy D. Bryant, inventor (to NASA) (Army Vehicle Structures Lab., Hampton, VA.) 4 Oct. 1994 25 p
(NASA-Case-LAR-14240-1; NAS 1.71:LAR-14240-1;
US-Patent-Appl-SN-319142) Avail: CASI HC A03/MF A01

An apparatus and method for bonding a first film to a second film to form a sensor. The first and second films are piezoelectric films. A base section has a mating surface for holding the first film. A top section has a mating surface for holding the second film, the top section and base section being mateable together to form a cavity between the top section mating surface and the base section mating surface with the first film and the second film pressed together inside the cavity to bond the first film to the second film. An internal connection port forming mechanism forms an internal connection port between the first film and the second film when the base section and top section are mated together with the first film and the second film pressed together inside the cavity. Alternately, an internal connection tab forming mechanism can be used to form a sensor having an internal connection tab between the first and second film, instead of having an internal connection port. Today's understanding of the molecular-level structure of inorganic glasses has been transformed by the availability of a wide range of sensitive spectroscopic probes. Today we can relate glass composition to quantitative distributions of glass-forming cations and to changes in oxygen bonding and modifying cation geometries. Future spectroscopic studies will result in improved descriptions of anion and cation geometries and should provide glass scientists with the capability to optimize atomic arrangements for specific optical, electrical, and thermal properties. NOVEL THIN-FILM CuInSe2 FABRICATION
A. M. Gabor (Colorado Univ., Boulder, CO.) and A. M. Hermann (Colorado Univ., Boulder, CO.) Aug. 1994 18 p
(Contract DE-AC36-83CH-10093)
(DE94-011874; NREL/TP-451-7055) Avail: CASI HC A03/MF A01

This report describes work exploring a new technique for the formation of CuIn(x)Ga(1-x)Se2 thin films. The Cu deposition was separated from the

Ga+In deposition such that precursor films with compositions of either Cu(x)Se or (In(x)Ga(1-x))2Se3 were formed. These precursors were exposed to either (1) In+Ga+Se or (2) Cu+Se at substrate temperatures greater than 500 C to form GaIn(x)Ga(1-x)Se2. Films made from the Cu(x)Se precursors were unexceptional, but films made from the (In(x)Ga(1-x))2Se3 precursors were of exceptional smoothness and density. During the period covered in this report, a device made from one of these films resulted in what, at the time, was the highest total-area efficiency measured for any non-single-crystal, thin-film solar cell, at 15.9%. FRACTURE ANALYSIS OF AN ALL-CERAMIC BEARING SYSTEM Final Report

Jeffrey A. Swab and Mary P. Sweeney Sep. 1994 40 p
(AD-A285056; ARL-TR-512) Avail: CASI HC A03/MF A01

The report summarizes the fracture mechanism of an all-ceramic duplex spin bearing which was tested to failure to establish a design load margin. This bearing is part of a gyro-optics assembly being developed for use in an infrared seeker. The analysis revealed that machining-induced microcracks grew in the inner raceways beneath a ball. These microcracks coalesced to form macrocracks which led to fracture of the inner race and the failure of the bearing system. DTIC

PHYSICAL-CHEMICAL STUDIES ON RODLIKE POLYMER COMPOSITIONS Final Report

G. C. Berry 20 Sep. 1994 65 p
(Contract F49620-92-J-0281)
(AD-A285361; AFOSR-94-0634TR) Avail: CASI HC A04/MF A01

Third harmonic generation (THG) is used to study the third-order nonlinear optical properties of nematic and isotropic solutions of poly(phenylene benzobisthiazole), PBZT, and related small molecule model compounds. Maker fringe patterns (MFP) for isotropic preparations are analyzed in terms of postulated surface layers comprising regions in which the rodlike chains tend to have their axes parallel to the plane of the surface, creating a negatively birefringent uniaxial nematic layer. The THG with the nematic solution exhibits intensity with polarization components unexpected for uniaxial nematic symmetry, along with other unexpected features in the MFP. This behavior is attributed to the effects of surface layers, postulated to exhibit biaxial nematic symmetry, in which the uniaxial nematic symmetry is broken in regions on the scale of a wavelength. Features of the texture of the nematic phase of PBZT solutions are discussed. The nature of twist-loop defects in the texture is described, along with certain defects in the form of an ellipsoid of revolution, postulated to result from a molecular weight fractionation in the heterodisperse polymer. Light scattering studies on dilute solutions of a poly(n-dodecyl thiophene) are given to elucidate supramolecular structure that leads to a thermochromic effect. The supramolecular structure may play a role in the molecular organization in the solid state, with influence on electronic and nonlinear optical behavior. DTIC

Wallura (Kernforschungsanlage, Juelich, Germany.), and V. Philipps (Kernforschungsanlage, Juelich, Germany.) Jan. 1994 23 p Presented at the 6th International Conference on Fusion Reactor Materials, Stresa, Italy, 27 Sep. - 1 Oct. 1993 Submitted for publication
(Contract DE-AC03-89ER-51114)
(DE94-017976; GA-A-21295; CONF-930928-30) Avail: CASI HC A03/MF A01

In the effort to evaluate boron-rich coatings as plasma facing surfaces in fusion devices, a new process for applying boron carbide (B4C) coatings to graphite was developed. The process entails eutectic melting of the carbon (C) substrate surface with a precursor layer of B4C particles. Adherent coatings were achieved which consisted of two layers: a surface layer and a graded penetration zone in the outer portion of the substrate. The surface-layer microstructure was multiphase and ranged from reaction-sintered structures of sintered B4C particles in an eutectic-formed matrix to that of hypereutectic carbon particles in a B4C-C eutectic matrix. Because of high surface energy, the coating generally developed a nonuniform thickness. Quantitative evaluations of the coating were performed with limiters in the TEXTOR fusion device and with coupons in electron beam tests. Test results revealed the following: good adherence of the coating even after remelting; and, during remelting, diagnostics detected a corresponding interaction of boron with the plasma. DOE

WATER-SOLUBLE POLYPHOSPHAZENES AND THEIR HYDROGELS

Harry R. Allcock 18 May 1994 53 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-91-J-1194)
(AD-A279695; TR-20) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Water-soluble polymers and hydrogels are important in areas as varied as biomedicine adhesion, membranes, and viscosity enhancement. They are possible replacements in technology and medicine for many naturally-occurring polymers. Unfortunately, relatively few of the hundreds of known synthetic polymers are soluble in water. Thus, the design and synthesis of new water-soluble polymers or hydrogels is a subject of considerable interest. This chapter is a review of an approach to this problem. DTIC

MORPHOLOGY OF HIGHLY TEXTURED E/EP DIBLOCK COPOLYMERS

P. Kofinas and R. E. Cohen 26 May 1994 35 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-91-J-1045)
(AD-A279813) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

A series of semicrystalline triblock copolymers E/EP/E, of poly(ethylene) (E) and poly(ethylene-propylene) (EP) were subjected to high levels of plane strain compression using a channel die. The processing was carried out at 150 C, a temperature which lies well above both the E block melting points (99-103 C) and the quiescent order-disorder transitions (ca. 106 C) for these samples. The lamellar orientation relative to the specimen boundaries was determined using two dimensional small-angle X-ray scattering. Using a 2.4 MPa applied stress on the channel die, the lamellae orient parallel to the plane of shear, while processing at an applied stress of 8.0 MPa causes the lamellae to orient perpendicular to the plane of shear. Gas permeability coefficients P for He and carbon dioxide were measured at 25 C for E/EP/E 25/50/25 specimens and compared to modeling predictions. The upper bound (lamellae aligned in parallel with respect to the permeation direction) and lower bound (series lamellar alignment) models were compared to experimental permeation data on the corresponding oriented triblock specimens. EFFECT OF EXTERNAL STRESS ON THE TRANSPORT OF FLUIDS IN THERMOPLASTIC RESIN SYSTEMS Final Report, 1 Mar. 1993 - 28 Feb. 1994
Clarence T. Wolf Apr. 1994 89 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract F49620-93-1-0196)
(AD-A279993; AFOSR-94-0314TR) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The transport properties of liquid penetrants into the thermoplastic resin, poly aryl ether ether ketone (PEEK) were investigated. The primary objective of this work was to study the effect of external applied stress on the diffusion and solubility/swelling of fluids with PEEK. The solubility and rate of penetration, i.e., diffusion, into the resin system are greatly increased by the application of stress: we call this phenomenon SEDS (stress enhanced diffusion and solubility/swelling). All eight fluids studied, benzene, toluene, methylene chloride, chloroform, carbon disulfide, methanol, acetone, and even water exhibit SEDS. The effect is particularly striking for crystalline PEEK where the solubility is markedly increased and the time to reach saturation, i.e., the induction period is reduced when the applied stress exceeds a critical value. For example, at 22 C the solubility of toluene into 29% crystalline PEEK increases from 9 wt% to almost 40 wt% upon the application of a tensile stress of 35 MPa. Furthermore, the time for 0.25 mm thick crystalline PEEK film to reach its saturation value was reduced from 1000's of hours to less than 10 hours. DTIC

STRUCTURAL PERFORMANCE OF CYLINDRICAL PRESSURE HOUSINGS OF DIFFERENT CERAMIC COMPOSITIONS UNDER EXTERNAL PRESSURE LOADING. PART 1: ISOSTATICALLY PRESSED ALUMINA CERAMIC Final Report
R. P. Johnson, R. R. Kurkchubasche, and J. D. Stachiw Aug. 1993 99 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A279669; NCCOSC/RDT/E-TR-1590-Pt-1) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Ten monocoque cylinders, 18-inches (length) by 12-inches (outer diameter, OD) by 0.412 inches (thickness), fabricated from 96-percent alumina ceramic were assembled into external pressure housings and experimentally evaluated under short-term, static, and cyclic pressure loadings. This study was undertaken as part of a program to promote the application of ceramics to large external pressure housings for underwater vehicles. Pressure testing was performed to generate structural performance data that could be used to establish design criteria for external pressure housings constructed by using 96-percent alumina ceramic as the primary hull material. Design curves for 96-percent alumina-ceramic housings are presented that relate the maximum number of operational dive cycles to the maximum allowable stresses in the ceramic housing during each dive cycle. The 96-percent alumina ceramic has been found to be a reliable structural material for the fabrication of cylindrical external pressure housings with a minimum fatigue life of 1,000 dive cycles to nominal design stresses of - 160,000 psi in the hoop direction. FERROIC MATERIALS: DESIGN, PREPARATION AND CHARACTERISTICS. CERAMIC TRANSACTIONS, VOLUME 43
A. S. Bhalla, K. M. Nair, I. K. Lloyd, H. Yanagida, and D. A. Payne 10 Nov. 1993 437 p Symposium held in Honolulu, HI, 7-10 Nov. 1993
(Contract N00014-93-1-0366)
(AD-A285937) Avail: CASI HC A19/MF A04

Ferroic materials have found application in both sensing and actuating devices such as detectors, high- and low-frequency transducers, capacitors, optical modulators, shutters, and photorestrictive and electrostrictive devices. The application areas of ferroics in single-crystal, bulk ceramics, thin-film, and composite forms have been expanding quite rapidly in recent years. As a result, new materials design and fabrication techniques are needed to satisfy the new emerging applications of these 'smart' materials and structures. With the drive of new national and international initiatives in the areas of advanced materials and technology, smart structures and systems, environmental benefication programs, etc., it is highly desirable to review and project the direction in materials design, preparation, and sensing properties. INORGANIC-ORGANIC POLYMERS AND THEIR ROLE IN MATERIALS SCIENCE
Harry L. Allcock 18 May 1994 39 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-91-J-1194)
(AD-A279715; TR-19) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The design and synthesis of new materials are two of the key steps in the advancement of technology. Significant advances in nearly all fields of advanced technology depend almost completely on the rate at which useful new materials can be devised and synthesized. One of the most promising approaches to the development of new materials that combine the advantages of organic polymers with those of inorganic solids is to devise polymers that have a backbone of inorganic atoms to which are attached organic or organometallic groups. Some inorganic-organic polymer systems are discussed. DTIC

AEROSOL-ASSISTED CHEMICAL VAPOR DEPOSITION OF COPPER: A LIQUID DELIVERY APPROACH TO METAL THIN FILMS
Thomas S. Corbitt, Mark J. Hampden-Smith, T. T. Kodas, and C. Roger 6 May 1994 14 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-91-J-1258)
(AD-A279702; TR-12) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Aerosol-Assisted Chemical Vapor Deposition (AACVD) has been used to attain high deposition rates (1000 A/min, up to 800 A/min at 140 C) of Cu films at low temperatures (120-200 C) from toluene solutions of (hfac)Cu(1,5-COD) in a warm-wall reactor. The films are crystalline and exhibit resistivities close to bulk (1.7-3.5 micro omega cm). Activation energies calculated from the deposition rate as a function of the preheating temperature and the substrate temperature (varying also the nozzle-substrate distance) were 6.8, 8.9 (0.7 cm) and 9.1 (1.7 cm) kcal/mol, respectively. EFFECT OF FIBER FABRIC ORIENTATION ON THE MONOTONIC AND FATIGUE BEHAVIOR OF A CONTINUOUS FIBER CERAMIC COMPOSITE

N. Chawla (Tennessee Univ., Knoxville, TN.), P. K. Liaw (Tennessee Univ., Knoxville, TN.), E. Lara-Curzio, R. A. Lowden, and M. K. Ferber 1994 16 p Presented at the The Metallurgical Society (TMS) Conference on High Performance Composites, Rosemont, IL, 10-15 Oct. 1994
(Contract DE-AC05-84OR-21400)
(DE94-018121; CONF-9410184-1) Avail: CASI HC A03/MF A01

The monotonic fast fracture and fatigue behavior of a Nextel(trademark) 312 reinforced SiC matrix composite was investigated. Effect of fabric orientation with respect to the loading axis on the monotonic and fatigue behavior of the composite was examined. Two geometries were investigated: transverse, where fiber fabric is perpendicular to loading direction; and edge-on where the fabric is parallel to the loading axis. The edge-on geometry showed higher flexure strengths than the transverse orientation. The different deformation mechanisms between the edge-on and transverse orientations were due to strong in-plane shearing of the fiber fabric and weak interlaminar shear of the plies, respectively. In cyclic fatigue, stress versus cycles (S-N) curves showed high fatigue endurance limits in both orientations, although the transverse orientation survived more cycles than the edge-on orientation at stresses slightly above the endurance limit. APPROACHES TO THE DESIGN OF STRUCTURAL CERAMICS INCORPORATING WHISKERS AND PARTICULATE PHASES

P. F. Becher, H. T. Lin, C. H. Hsueh, K. B. Alexander, W. H. Warwick, and S. B. Waters 1994 4 p Presented at the 3d Conference on Ceramic-Ceramic Composites, Mons, Belgium, 18-20 Oct. 1994
(Contract DE-AC05-84OR-21400)
(DE94-018126; CONF-941059-1) Avail: CASI HC A01/MF A01

Advances in the technologically and commercially important areas of energy production and conversion, transportation, chemical processing, manufacturing, electronics, and communications are predicted upon the development of materials with greatly improved performance. Many of these components will be exposed to tensile stresses, and possibly quite high temperatures, which will require that the materials be designed to (1) achieve greater fracture resistance, (2) resist deformation at elevated temperatures, and (3) achieve the main component function. Here, theoretical modeling and observations of crack propagation in ceramics and composites are combined to identify and characterize mechanisms that contribute to fracture resistance and strength. Materials processing studies can then be employed to (1) develop the microstructural features suggested by the models and (2) understand the mechanisms involved in the generation of such microstructures. In this paper, the authors address how these various aspects can be used to enhance the mechanical performance of zirconia toughened ceramics (specifically involving transformation toughening) and whisker-reinforced ceramics with comments on other composites incorporating other discontinuous phases. CROSS-LINKING REACTIONS FOR THE CONVERSION OF POLYPHOSPHAZENES INTO USEFUL MATERIALS

Harry R. Allcock 18 May 1994 98 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-91-J-1194)
(AD-A279696; TR-23) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The conversion of phosphazene high polymers to useful materials depends on the development of methods to cross-link the macromolecular chains. A number of cross-linking routes have been used, including chemical, photochemical, and high energy radiation techniques. The relationship of the cross-linking processes to electrochemical-, electrooptical-, elastomer-, structural-, membrane-, surface-, and biomedical properties is discussed. DTIC

MATERIALS PROCESSING USING A VARIABLE FREQUENCY MICROWAVE FURNACE

R. J. Lauf, D. W. Bible, S. R. Maddox, C. A. Everleigh (Microwave Labs., Inc., Raleigh, NC.), R. J. Espinosa (Microwave Labs., Inc., Raleigh, NC.), and A. C. Johnson (Microwave Labs., Inc., Raleigh, NC.) 1993 9 p Presented at the 95th Annual Meeting of the American Ceramic Society, Cincinnati, OH, 18-22 Apr. 1993
(Contract DE-AC05-84OR-21400)
(DE95-001420; CONF-930438-33) Avail: CASI HC A02/MF A01

We describe a materials processing system that uses a high power traveling wave tube (TWT) as the microwave source. The TWT provides approximately one octave bandwidth and variable power levels up to 2 kW into a multimode cavity. By controlling the frequency, efficient coupling to the load can be maintained even as the load's dielectric properties change. Alternatively, frequency sweeping can be used as a means of mode stirring at rates far beyond those attainable through mechanical stirring. The system has been tested for sintering alumina ceramics, annealing a tungsten penetrator alloy, curing epoxy resin, and depositing diamond films from a microwave plasma. DOE

THE NUMERICAL INTEGRATION AND 3-D FINITE ELEMENT FORMULATION OF A VISCOELASTIC MODEL OF GLASS

R. S. Chambers Aug. 1994 66 p
(Contract DE-AC04-94AL-85000)
(DE95-002588; SAND-94-1607) Avail: CASI HC A04/MF A01

The use of glasses is widespread in making hermetic, insulating seals for many electronic components. Flat panel displays and fiber optic connectors are other products utilizing glass as a structural element. When glass is cooled from sealing temperatures, residual stresses are generated due to mismatches in thermal shrinkage created by the dissimilar material properties of the adjoining materials. Because glass is such a brittle material at room temperature, tensile residual stresses must be kept small to ensure durability and avoid cracking. Although production designs and the required manufacturing process development can be deduced empirically, this is an expensive and time consuming process that does not necessarily lead to an optimal design. Agile manufacturing demands that analyses be used to reduce development costs and schedules by providing insight and guiding the design process through the development cycle. To make these gains, however, viscoelastic models of glass must be available along with the right tool to use them. A viscoelastic model of glass can be used to simulate the stress and volume relaxation that occurs at elevated temperatures as the molecular structure of the glass seeks to equilibrate to the state of the supercooled liquid. The substance of the numerical treatment needed to support the implementation of the model in a 3-D finite element program is presented herein. An accurate second-order, central difference integrator is proposed for the constitutive equations, and numerical solutions are compared to those obtained with other integrators. Inherent convergence problems are reviewed and fixes are described. The resulting algorithms are generally applicable to the broad class of viscoelastic material models. First-order error estimates are used as a basis for developing a scheme for automatic time step controls, and several demonstration problems are presented to illustrate the performance of the methodology. EXPERIMENTAL INVESTIGATION OF WAVE AND FRACTURE PHENOMENA IN IMPACTED CERAMICS Final Report
E. Strassburger and H. Senf Jun. 1994 55 p
(Contract DAJA45-90-C-0053)
(AD-A286589; R/D-6472-MS-01) Avail: CASI HC A04/MF A01

Four types of glass which differ in their chemical composition, hardness and material density and tiles of SiC, TiB2, and Al2O3 were impacted edge-on with blunt steel projectiles at striking velocities between 20 m/s and 1000 m/s. The propagation of shock waves, of primary and secondary cracks and crack systems and the growing of crack systems from nucleated centers were visualized by means of a Cranz-Schardin high-speed camera within the first twenty microseconds, before the projectile penetrated the target more than a few millimeters. The concept of damage velocity was introduced to describe the different damage processes quantitatively. All four types of glass reveal a similar behavior. The damage velocity equals terminal crack velocity at low loadings. Other than in glass, in the ceramics different types of cracks are generated and different fracture velocities were observed at one impact velocity of continuously growing cracks, including the secondary cracks with sharp edges, fuzzy crack traces and crack fronts. In each of the ceramics the damage velocity increases with increasing striking velocity and approaches the longitudinal wave velocity at high loadings. A terminal crack velocity was found for one type of fracture in SiC. Ceramographical investigations of TiB2 fragments have shown that cracks within large grains as well as intercrystalline cracks are generated by coalescence of voids. DTIC

CHARACTERIZATION AND ELECTRICAL PROPERTIES OF COPPER FILMS GROWN VIA DIRECT LIQUID COINJECTION OF (hfac)Cu(TMVS) AND TMVS
John E. Parmeter, Gary A. Petersn, Christopher A. Apblett, and Paul Martin Smith Oct. 1994 30 p
(Contract DE-AC04-94AL-85000)
(DE95-002957; SAND-94-1716) Avail: CASI HC A03/MF A01

This report documents the characterization of thin copper films grown at Sandia as part of on-going research in copper CVD involving Sandia and Schumacher, Inc. The films have been grown using the copper (1) CVD precursor (hfac)Cu(TMVS), which was first developed by Schumacher and has been supplied to Sandia by that company. The CVD was performed using a novel technique in which direct liquid coinjection of (hfac)Cu(TMVS) and TMVS (trimethylvinylsilane) into a commercial reactor is utilized. Films were deposited onto silicon nitride substrates at temperatures in the range of 220C-250C, with growth rates in the range of 400A-800A/min. These films have been analyzed by a variety of techniques, with an emphasis on factors that may influence the resistivity, including thickness, purity, density, grain size, and stress. The authors show that these films have as-deposited resistivities of 1.86 +/- 0.1 microohm-cm, or 1.82 +/- 0.1 microohm-cm after accounting for surface scattering effects. The latter value is only 0.14 microohm-cm above the value for high purity bulk copper. The authors discuss factors that may account for this residual resistivity. They also discuss the effects of film surface roughness on film thickness and resistivity measurements, noting some potential problems associated with the commonly used surface profilometry technique. These results help to establish (hfac)Cu(TMVS) as one of the most promising available copper CVD precursors for metallization applications. DOE

SPUTTER DEPOSITION OF MULTILAYER THERMOELECTRIC FILMS: AN APPROACH TO THE FABRICATION OF TWO-DIMENSIONAL QUANTUM WELLS
J. C. Farmer, T. W. Barbee, Jr., G. C. Chapline, Jr., R. J. Foreman, L. J. Summers, M. S. Dresselhaus (Massachusetts Inst. of Tech., Cambridge, MA.), and L. D. Hicks (Massachusetts Inst. of Tech., Cambridge, MA.) Jul. 1994 11 p Presented at the 13th International Conference on Thermoelectrics, Kansas City, MO, 30 Aug. - 1 Sep. 1994
(Contract W-7405-eng-48)
(DE95-002396; UCRL-JC-117602; CONF-940830-2) Avail: CASI HC A03/MF A01

The relative efficiency of a thermoelectric material is measured in terms of a dimensionless figure of merit, ZT. Though all known thermoelectric materials are believed to have ZT less than or equal to 1, recent theoretical results predict that thermoelectric devices fabricated as two-dimensional quantum wells (2D QW's) or one dimensional (1D) quantum wires could have ZT greater than or equal to 3. Multilayers with the dimensions of 2D QW's have been synthesized by alternately sputtering Bi0.09Sb0.1 and PbTe0.8Se0.2 onto a moving single-crystal sapphire substrate from dual magnetrons. These materials have been used to test the thermoelectric quantum-well concept and gain insight into relevant transport mechanisms. If successful, this research could lead to thermoelectric devices that have efficiencies close to that of an ideal Carnot engine. Ultimately, such devices could be used to replace conventional heat engines and mechanical refrigeration systems. DOE

POLYMER BASED ALL-OPTIC RECONFIGURABLE INTERCONNECTS Final Report, 1 Jul. - 31 Dec. 1993
Tomasz Jannson 28 Feb. 1994 45 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract F49620-93-C-0046)
(AD-A279976; AFOSR-94-0313TR) Avail: CASI HC A03

In Phase 1 of this project, POC successfully implemented a prototype all-optic reconfigurable polymer-based crossbar switch. POC's all-optic reconfigurable polymer-based crossbar switch represents a unique combination of polymer techniques, simple geometry optics, and waveguide technology. These three essential technologies are original POC developments. POC's crossbar switch will provide reconfigurability, large fan-out, and radiation hardening. This is a new technology for both parallel and distributed processing and communication networks. The Phase 1 results have shown that POC's crossbar switch can offer a number of important advantages not achievable by either electronic interconnects or currently existing all-optic reconfigurable interconnects. These advantages include: (1) very low power sources (-100 mW); (2) relatively high interconnect reconfigurability time; (3) high data rates over 1 Gb/sec; (4) low bit error rate (less than 10(exp -10)); (5) very large fan-out capability (less than 1000 channels); (6) very low manufacturing cost; and (7) very high erasability. It is expected that POC's crossbar switch performance will be superior to existing electronic and optical interconnection approaches. In Phase 1, POC also demonstrated the feasibility of commercialization in the area of multimedia, video conferencing, and other communication applications. DTIC

MICROMECHANICAL APPROACH TO TRANSFORMATION TOUGHENING IN CERAMICS Ph.D. Thesis

G. Stam 12 Sep. 1994 61 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(PB95-135422; ISBN-90-370-0106-8) Avail: CASI HC A04

In the thesis, the authors have presented numerical studies of transient crack growth in ceramic composites exhibiting transformation-plasticity based on the recent model of Sun et al. (1991) that includes the effect of transformation-induced dilatation as well as shear. The authors' analyses supplement those of Hom and McMeeking (1990) who considered only dilatational transformations. The finite element results obtained here with the Sun et al. (1991) model show a very significant influence of the transformation shear strains on the transformation zone size and shape, as well as on the toughness development during crack growth. An increasing influence of the shear effect, as governed in the model by the parameter h(sub 0), roughly speaking, leads to larger and more diffuse transformation zones. The increase of toughness with increasing value of h(sub 0) has been found to be quite substantial as compared with the toughness increase that is obtained by purely dilatational transformation only. For values of h(sub 0) between 1 and 1.5, which are representative for ZrO2 composites, the authors have found increases in toughness that are 4 to 8 times larger than without transformation-induced shear strains. Since, so far, dilatant transformation-based theory has underestimated the toughness enhancement found in experiments, the present results with transformation-induced shear effects contribute to explaining this difference. Polyphosphazenes are among the most versatile of all polymers. This is a consequence of the unique properties of the phosphorus-nitrogen backbone and the ease with which a wide range of different side groups can be introduced mainly by macromolecular substitution, but also by the polymerization of different monomers. This field has reached a stage where the fundamental chemistry now allows the design and synthesis of a broad range of new materials that are valuable for properties such as elasticity, high refractive index, liquid crystallinity, ferroelectric-, NLO-, and photochromic attributes, and for uses as solid ionic conductors, biomedical microencapsulation polymers, and materials with controlled surface properties. CONDUCTING THERMOSET POLYMERS Annual Technical Report, 1 Oct. 1993 - 30 Sep. 1994

I. M. Brown, D. J. Leopold, and T. C. Sandreczki 20 Oct. 1994 44 p
(Contract F49620-92-C-0074)
(AD-A286541; MDC-94X0025; AFOSR-94-0711TR) Avail: CASI HC A03/MF A01

Continuing efforts to develop conducting thermoset polymers in which the Pi-conjugation extends along the backbone and through the crosslink are described. Acetylene terminated Schiff bases, acetylene-terminated polythiophenes and acetylene-terminated polyanilines are being investigated. Two different approaches to get these thermosets conducting are being pursued: in the AT-Schiff bases and AT-polythiophenes the monomers are first cured then doped with iodine, whereas in the AT-polyanilines the oligomers are first doped with protonic acids then cured. Electron spin resonance, photoluminescence and photo-absorption data suggest that polarons can form in the doped and undoped forms of the AT-Schiff bases and AT-polythiophenes. The dependences of the ESR lineshape parameters of the AT-Schiff bases and amine-cured epoxies on iodine content can be explained in terms of a model involving equilibria between polymeric radical cation complexes containing different stoichiometric amounts of iodine. Several AT-polyanilines oligomers containing either alkoxy substituents or meta substitution in the backbones were synthesized in order to improve the possibility of thermosets. These oligomers were doped with different organic acids. The maximum conductivity value measured was 2 x 10 (exp -2) S/cm. DTIC

MICROSTRUCTURAL DESIGN FOR TOUGH CERAMICS Final Report

Helen M. Chan and Brian R. Lawn Oct. 1994 144 p
(Contract F49620-92-J-0039)
(AD-A285634; AFOSR-94-0652TR) Avail: CASI HC A07/MF A02

Results of a program on the influence of microstructure on the toughness and fatigue properties of ceramics are presented. A theoretical analysis of toughness-curve behavior in two-phase ceramics has been completed. This analysis identifies particle size, volume fraction, and internal thermal expansion anisotropy stress as key microstructural variables in the toughness response. A simple contact fatigue methodology for investigating the accumulation of damage at stress concentrations in tough ceramics, using the Hertzian indentation test in cyclic loading, has been developed. This methodology offers several advantages over traditional long-crack fatigue testing, and relates directly to the stress states that occur in contact bearings. Optical and acoustic emission tests reveal fundamental departures from the classic cone fractures that form in homogeneous brittle materials. Instead, a new kind of damage, shear-initiated microfractures in a distributed zone directly beneath the contact area is observed. The damage thereby occurs in the short-crack region, and is most severe in those ceramics that show the highest long-crack toughness, underlying the need for compromise in materials design. The results bear strongly on such practical properties as bearing fatigue, and strength, wear and erosion of structural ceramics. DTIC

(Contracts W-7405-eng-48; DE-AC03-76SF-00098)
(DE94-015560; UCRL-JC-117440; CONF-9409177-1) Avail: CASI HC A02/MF A01

The need for normal incidence mirrors maintaining reflectivity greater than 60% for an industrially competitive Extreme Ultraviolet Lithography (EUV) system has been well documented. The Molybdenum/Silicon system has emerged as the de-facto standard, where researchers are now routinely fabricating mirrors demonstrating 63% reflectivity near 130 Angstroms. However, multilayer mirrors using beryllium as the low atomic number (low-Z) spacer could potentially show similar or better reflectivity, and operate at wavelengths down to the beryllium K-edge at 111 Angstroms. Besides offering potentially greater reflectivity, the shorter wavelength light offers increased dissolution depth in photoresists, and offers potentially better resolution and depth of focus. We will report our latest results from beryllium based multilayers. The mirrors were fabricated at the Lawrence Livermore National Laboratory (LLNL) and tested at the Center for X-Ray Optics at Lawrence Berkeley Laboratory (CXRO/LBL). DOE

AN INVESTIGATION OF THE APPLICABILITY OF THE NEW ION EXCHANGE RESIN, REILLEX(TM)-HPQ, IN ATW SEPARATIONS
Milestone 4 Final Report
Kenneth R. Ashley, Jason Ball, Melissa Grissom, Michelle Williamson, Stephen Cobb, Daniel Young, and Yen-Yuan James Wu 7 Sep. 1993 156 p Sponsored by DOE
(DE94-016576; LA-SUB-94-106) Avail: CASI HC A08/MF A02

The investigations with the anion exchange resin Reillex(TM)-HPQ is continuing along several different paths. The topics of current investigations that are reported here are: (1) The sorption behavior of chromium(6) on Teillex(TM)-HPQ from nitric acid solutions and from sodium hydroxide/sodium nitrate solutions; (2) The sorption behavior of F(-) on Reillex(TM)-HPQ resin in acidic sodium nitrate solution; (3) The sorption behavior of Cl(-) on Reillex(TM)-HPQ resin in acidic sodium nitrate solution; (4) The sorption behavior of Br(-) on Reillex(TM)-HPQ resin in acidic sodium nitrate solution; and (5) The Honors Thesis by one of the students (which is attached to Appendix 2). FRICTION AND WEAR PROPERTIES OF AS-DEPOSITED AND CARBON ION-IMPLANTED DIAMOND FILMS
Kazuhisa Miyoshi Feb. 1994 26 p Presented at the Fifth International Conference onthe Science of Hard Materials, Maui, Hawaii, 20-24Feb. 1995; sponsored by ICSHM-5 Organizing Committee
(RTOP 505-63-5A)
(NASA-TM-106759; E-9194; NAS 1.15:106759) Avail: CASI HC A03/MF A01

Recent work on the friction and wear properties of as-deposited and carbon ion-implanted diamond films was reviewed. Diamond films were produced by the microwave plasma chemical vapor deposition (CVD) technique. Diamond films with various grain sizes and surface roughnesses were implanted with carbon ions at 60 ke V ion energy, resulting in a dose of 1.2310(exp 17) carbon ions/cm(exp 2). Various analytical techniques, including Raman spectroscopy, proton recoil analysis, Rutherford backscattering, transmission and scanning electron microscopy, x-ray photoelectron spectroscopy, and x-ray diffraction, were utilized to characterize the diamond films. Sliding friction experiments were conducted with a polished natural diamond pin in contact with diamond films in the three environments: humid air (40 percent relative humidity), dry nitrogen (less than 1 percent relative humidity), and ultrahigh vacuum (10(exp -7) Pa). The CVD diamond films indeed have friction and were properties similar to those of natural diamond in the three environments. The as-deposited, fine-grain diamond films can be effectively used as self-lubricating, wear-resistant coatings that have low coefficients of friction (0.02 to 0.04) and low wear rates (10(exp -7) to 10(exp -8)mm(exp 3)/N-m) in both humid air and dry nitrogen. However, they have high coefficients of friction (1.5 to 1.7) and a high wear rate (10(exp -4)mm(exp 3/N-m) in ultrahigh vacuum. The carbon ion implanation produced a thin surficial layer (less than 0.1 micron thick) of amorphous, nondiamond carbon on the diamond films. In humid air and dry nitrogen, the ion-implanted, fine- and coarse-grain diamond films have a low coefficient of friction (around 0.1) and a low wear rate (10(exp -7)mm(exp 3/N-m). Even in ultrahigh vacuum, the presence of the nondiamond carbon layer reduced the coefficient of friction of fine-grain diamond films to 0.1 or lower and the wear rate to 10(exp -6)mm(exp 3)/N-m. Thus, the carbon ion-implanted, fine-grain diamond films can be effectively used as wear-resistant, self-lubricating coatings not only in air and dry nitrogen, but also in ultrahigh vacuum. The wear mechanism of diamond films is that of small fragments chipping off the surface. The size of wear particles is related to the extent of wear rates. Author

NONLINEAR OPTICAL STUDIES OF POLYMER INTERFACES
Y. R. Shen Nov. 1993 19 p Presented at the POLIMEX 1993 Symposium, Cuncum Quintana Roo, Mexico, 1-3 Nov. 1993
(Contract DE-AC03-76SF-00098)
(DE94-018199; LBL-35308; CONF-9311234-1) Avail: CASI HC A03/MF A01

Second-order nonlinear optical processes can be used as effective surface probes. They can provide some unique opportunities for studies of polymer interfaces. Here the author describes two examples to illustrate the potential of the techniques. One is on the formation of metal/polymer interfaces. The other is on the alignment of liquid crystal films by mechanically rubbed polymer surfaces. DOE

COMPATIBILITY TESTING OF EXPLOSIVES AND PAINTS BY CHEMILUMINESCENCE TECHNIQUES [FOERENLIGHETSUNDERSOEKNINGAR FOER NAGRA EXPLOSIVAEMNEN OCH FAERGER MED HAELP AV KEMILUMINISCENS OCH MIKROKALORIMETRI]

M. Hihkioe and G. Aqvist Jun. 1994 21 p In SWAHILI
(PB95-133609; FOA-C-20986-2.3) Avail: Issuing Activity (National Technical Information Service (NTIS))

An equipment developed for analysis of propellants using chemilumescence reaction between nitric oxide and ozone has been used. The high sensitivity of the method makes it possible to carry out measurements at temperature close to normal storing conditions. The work is a preliminary study of compatibility testing of explosives and paints by chemiluminescence techniques. Some results were also compared with microcalorimetric measurements. In the study, compatibility tests have been done with TNT, RDX, PETN, single base propellant and paints. The authors have investigated compatibility with paints because they are in direct contact with explosives in ammunition. Paints prevent ammunition from rusting and improve explosives to adhere to the shell. NTIS

THE FORMATION OF REACTION BONDED SI3N4 AT LOW TEMPERATURES AND IN SHORT TIMES

B. W. Sheldon and J. S. Haggerty 1994 15 p Presented at the 13th Annual Conference on Composites and Advanced Ceramics, Cocoa Beach, FL, 15-18 Jan. 1989
(Contract DE-FG02-87ER-45313)
(DE95-001990; CONF-890130-6) Avail: CASI HC A03/MF A01

The kinetics and mechanisms of nitriding high purity, SiH4 derived Si powders were investigated. TGA, X-ray diffraction, FTIR spectroscopy, and TEM techniques were employed. Complete nitridation (greater than 99%) was achieved at 1250 C in less than 10 minutes, and nearly complete nitridation (97%) was achieved at 1100 C in less than 5 hours. The effects of temperature, particle diameter, and surface chemistry were studied and results show that the process is principally controlled by the number of Si3N4 nuclei that form. Reduced temperature, increased Si particle diameter, and surface contamination all reduce the conversion rate through direct effects on nucleation. DOE

N95-21354# CeraMem Corp., Waltham, MA.

CERAMEM FILTERS FOR REMOVAL OF PARTICLES FROM HOT GAS STREAMS

Bruce A. Bishop and Robert L. Goldsmith 1994 11 p Presented at the Coal-fired Power Systems: Advances in IGCC and PFBC Review Meeting, Morgantown, WV, 21-23 Jun. 1994
(Contract DE-FG02-90ER-80896)
(DE95-001976; DOE/ER-80896/94/C0379; CONF-9406131-63) Avail: CASI HC A03/MF A01

The need for hot gas cleanup in the power, advanced coal conversion, process and incineration industries is well documented and extensive development is being undertaken to develop and demonstrate suitable filtration technologies. In general, process conditions include: (1) oxidizingor reducing atmospheres; (2) temperatures to 1800 F; (3) pressures to 300 psi; and (4) potentially corrosive components in the gas stream. The most developed technologies entail the use of candle or tube filters, which suffer from fragility, lack of oxidation/corrosion resistance, and high cost. The ceramic membrane filter described below offers the potential to eliminate these limitations. DOE

MONOMER MAPPING: A PC-BASED SOFTWARE TOOL FACILITATING THE DETERMINATION OF MONOMER COMPOSITIONS FROM MASS SPECTROMETRIC MOLECULAR WEIGHT DATA

D. C. vanSetten and G. vandeWerken Apr. 1994 38 p
(PB95-132155; RIVM-343605002) Avail: CASI HC A03/MF A01

A method to establish the monomer composition of (bio)macromolecules has been developed. The method, to be called monomer mapping, involves the mass spectrometric determination of the molecular weight and a computer program. The program generates monomer compositions corresponding to the measured molecular weight. If more than one monomer composition for the polymer is generated by monomer mapping, a further limitation can be obtained from the determination of the number of exchangeable hydrogens. Monomer mapping can be used to determine the monomer compositions of individual components in mixtures without applying (chromatographic) separation techniques. This is a clear advantage over methods involving monomerization and consecutive determination of the relative amounts of monomers. As a limitation, monomer mapping requires the elemental compositions of all monomer types possibly present in the polymer. NTIS

LEAD-INDIUM PHOSPHATE GLASSES FOR OPTICAL APPLICATIONS

B. C. Sales, L. A. Boatner, and S. W. Allison 1994 8 p Presented at the Annual Meeting of the Society of Photo-Optical Instrumentation Engineers, San Diego, CA, 24-29 Jul. 1994
(Contract DE-AC05-84OR-21400)
(DE94-019333; CONF-940723-29) Avail: CASI HC A02/MF A01

A new glass system based on a range of lead-indium phosphate compositions has been developed. These glasses have a relatively high index of refraction (1.8-1.9) in the visible region and exhibit moderate dispersion (typical Abbe number of 32). The ultraviolet absorption edge occurs near 300 nm and the glasses strongly absorb in the infrared at wavelengths greater than 2,800 nm. The glasses can be prepared at relatively low temperatures (900-1,000 C) and are easily poured at temperatures near 800 C due to their low melt viscosities. Lead-indium phosphate glasses exhibit good chemical durability and resistance to both weathering and intense gamma-irradiation. These materials have a glass transition temperature of 430 C, and thermal expansion coefficients in the range of 11 to 12 x 10(exp -6)/C. The structure of these glasses consists of a distribution of chains of PO4 tetrahedra held together by bonding between the non-bridging oxygen of the tetrahedra and the metal cations. The polyphosphate chain distribution was determined using the technique of high-performance liquid chromatography. The high index of refraction of lead-indium phosphate glasses makes them attractive for several applications such as high-numerical-aperture optical fibers and specialty lenses. Optical fibers up to 60 m in length have been drawn, and several simple lenses have been designed, ground, and polished. Preliminary results on the ability to directly case optical components of lead-indium phosphate glass are also discussed as well as the suitability of these glasses as a host medium for rare-earth ion lasers and amplifiers. COMPARISON OF PROPERTIES OF SINTERED AND SINTERED REACTION-BONDED SILICON NITRIDE FABRICATED BY MICROWAVE AND CONVENTIONAL HEATING

T. N. Tiegs, J. O. Kiggans, Jr., H. T. Lin, and C. A. Willkens (Norton Co., Northboro, MA.) 1994 6 p Presented at the Spring Meeting of the Materials Research Society, San Francisco, CA, 4-8 Apr. 1994
(Contract DE-AC05-84OR-21400)
(DE95-001426; CONF-940411-54) Avail: CASI HC A02/MF A01

A comparison of microwave and conventional processing of silicon nitride-based ceramics was performed to identify any differences between the two, such as improved fabrication parameters or increased mechanical properties. Two areas of thermal processing were examined: (1) sintered silicon nitride (SSN) and (2) sintered reaction-bonded silicon nitride (SRBSN). The SSN powder compacts showed improved densification and enhanced grain growth. SRBSN materials were fabricated in the microwave with a one-step process using cost-effective raw materials. The SRBSN materials had properties appropriate for structural applications. Observed increases in fracture toughness for the microwave processed SRBSN materials were attributable to enhanced elongated grain growth. DOE

THE DEVELOPMENT OF A NEW PLASTICIZER FOR POLY(ETHYLENE OXIDE) BASED POLYMER ELECTROLYTE AND THE INVESTIGATION OF THEIR ION-PAIR DISSOCIATION EFFECT

X. Q. Yang, H. S. Lee, L. L. Hanson, J. McBreen, and Y. Okamoto (Polytechnic Univ., Brooklyn, NY.) 1994 22 p Presented at the 7th International Meeting on Lithium Batteries, Cambridge, MA, 15-20 May 1994
(Contract DE-AC02-76CH-00016)
(DE94-016821; BNL-60652; CONF-940568-5) Avail: CASI HC A03/MF A01

One approach to increasing the ionic conductivity of polymer electrolyte is to add plasticizers to the polymer-salt complexes. Recently, we have synthesized a new plasticizer, modified carbonate (MC3), by attaching three ethylene oxide units to the four-position of ethylene carbonate. AC impedance studies showed that an ionic conductivity of 5 x 10(exp -5) S/cm could be achieved at room temperature, by adding 50 wt% of MC3 into PEO-LiCF3SO3 complex. This is two orders of magnitude higher than that found in PEO-LiCF3SO3 electrolyte without a plasticizer, and one order of magnitude higher than that found when using same amount of propylene carbonate (PC) as plasticizer. Temperature dependent conductivity measurement and thermal analysis show that this new plasticizer increased the ionic conductivity throughout the entire complex system, while the conventional plasticizers only create a high conductivity path way through the plasticizer itself. The samples are free standing films with good mechanical properties. When MC3 is used as a plasticizer, the ionic conductivity increase is much higher than using PC as a plasticizer at high temperature (65 C), implying an increase in the number of charge carriers. Therefore, we believe that MC3 has a stronger ion pair dissociation effect than PC, when used as a plasticizer. The ion pair dissociation effect was studied by Raman, FTIR, and near edge x-ray absorption fine structure (NEXAFS) spectroscopy. DOE

DEVELOPMENT AND APPLICATIONS OF FLAT CERAMIC MEMBRANES

C. Simon and R. Bredesen 13 May 1994 20 p
(PB95-110219; STF24-A94025) Avail: Issuing Activity (National Technical Information Service (NTIS))

The mechanical strength of flat ceramic membranes made by tape casting has been investigated and improved. The characteristics of the powders used to cast the substrate have shown to be related to the quality of the tape. The gas permeability of the substrate and the complete three layer membrane configuration have been measured for alumina membranes. It confirms that the porous gamma-Al2O3 top layer made by this technique are defect-free. The cut-off values of the top layer have been determined by using different molecular weight dextrans. The adsorption behavior of these molecules on the membrane surface material have been investigated. Finally, the membranes have been applied in the filtration of metal particles coming from the dissolution of an alumina alloy in butanol. NTIS

FORMING OF SUPERPLASTIC CERAMICS

D. R. Lesuer, J. Wadsworth, and T. G. Nieh May 1994 14 p Presented at the 8th International Context on Modern Materials Technologies, Faenza, Italy, 30 Jun. - 4 Jul. 1994
(Contract W-7405-eng-48)
(DE94-017306; UCRL-JC-117168; CONF-9406239-1) Avail: CASI HC A03/MF A01

Superplasticity in ceramics has now advanced to the stage that technologically viable superplastic deformation processing can be performed. In this paper, examples of superplastic forming and diffusion bonding of ceramic components are given. Recent work in biaxial gas-pressure forming of several ceramics is provided. These include yttria-stabilized, tetragonal zirconia (YTZP), a 20% alumina/YTZP composite, and silicon. In addition, the concurrent superplastic forming and diffusion bonding of a hybrid ceramic-metal structure are presented. These forming processes offer technological advantages of greater dimensional control and increased variety and complexity of shapes than is possible with conventional ceramic shaping technology. HIGH PERFORMANCE YBCO FILMS Report, 25 Feb. - 25 May 1994

Edgar J. Denlinger 25 May 1994 14 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-91-C-0216)
(AD-A279560) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

A Bi2O3-based glass composition was found suitable for use under typical YBCO deposition conditions, which is in a vacuum under partial oxygen pressure at about 750 C. It was experimentally determined that a Ag capping layer thickness of about 5 microns is needed for use with this glass. This Ag thickness will prevent any degradation in the silver layer's conducting properties due to Ag/glass interaction during the glass firing operation at 640 C. Lanthanum aluminate samples with YBCO topped with a thin layer of strontium titanate (STO) were prepared by Neocera and had excellent YBCO surface resistance properties as measured with a dielectric resonator test system. These samples will be used to test the compatibility of the YBCO with the silver capping layer deposited over the STO. DTIC

DOMAIN PROCESSES IN FERROELECTRIC CERAMICS Final Report, 30 Sep. 1991 - 31 Dec. 1993

Wenwu Cao and L. E. Cross 14 Apr. 1994 78 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Grant AF-AFOSR-0433-91)
(AD-A279567; AFOSR-94-0308TR) Avail: CASI HC A05

This report outlines the progress achieved during a two year effort sponsored by the AFOSR on the theoretical study of domain and domain wall formation in ferroelectrics. Understanding on domain formation and domain dynamics in ferroelectrics are crucial for developing better functional ceramic materials for transducers and actuators. A continuum model has been developed to describe the polarization profile in ferroelectrics, which takes into account both nonlinear and nonlocal nature of the ferroelectric system. The theory can give rise to twin and twin band solutions under proper boundary conditions. A theoretical model is also developed for the morphotropic phase boundary in PZT system, which provides a new interpretation on the phase coexistence in a complete solid solution system. According to the new definition, the width of the coexistence region is inversely proportional to the volume of the coherent region, such as the particle size for a fine grain system. Theoretical interpretation is provided to the electron interference pattern across a ferroelectric domain wall in holographic electron microscopy, a newly developed technique with much higher magnification than the conventional TEM. The relationship between microscopic lattice dynamics and the continuum theory is also established. DTIC

INVESTIGATION ON RESEARCH FOR DEGRADABLE PLASTICS
M. Nishiyama, J. Hosokawa, K. Yoshihara, T. Kubo, H. Kabeya, T. Endo, and R. Kitagawa 31 Mar. 1994 108 p
(DE94-796550; ETDE/JP-mf-94796550) Avail: CASI HC A06/MF A02

This paper investigates and reports problems on plastic waste and the measures to solve them, and the developmental trend of main biodegradable plastics in the world. A large quantity of plastic waste neither rots or returns to nature even if reclaimed. A recycling system has not yet been established due to plastics' low price. Therefore, countries are carrying out regulations to prohibit the use of foamed polystyrene, to enforce the compulsory use of degradable plastics, to create a taxation on plastic bottles, etc. Among biodegradable plastics, a type of polyethylene blended with starch is legislated for its use in the U.S., but it has been met with opposition by environmental organizations because it's plastic powder remains in the soil. Contrary to this partial degradability, the following are cited as completely degradable plastics: (1) bioplastics based on microorganism; (2) natural polymer based on plants and animals; and (3) biodegradable synthetic polymer. All of the m, however, are still in the early stages of research and development and commercialization. DOE

DIRECTIONAL SOLIDIFICATION OF THE ALUMINA-ZIRCONIA CERAMIC EUTECTIC SYSTEM Ph.D. Thesis
C. Boldt 27 Jul. 1994 95 p
(Contract W-7405-eng-82)
(DE95-001677; IS-T-1621) Avail: CASI HC A05/MF A01

It is possible to produce alumina-zirconia ceramic samples through existing solidification techniques. The resulting microstructures typically consist of rods of zirconia in an alumina matrix, although a lamellar structure has been noted in some cases. In nearly all cases, colony growth was present which may possibly result from grain size, repeated nucleation events, and lamellar oscillations. In the same vein, it appears that the amount of impurities within the system might be the underlying cause for the colony growth. Colony growth was diminished through impurity control as the higher purity samples exhibited colony free behavior. In addition to colony formations, faceted alumina dendrites or nonfaceted zirconia dendrites may result in the ceramic if the sample is solidified out of the coupled zone. In all cases, for larger-sized Bridgman samples, a lower limit in the eutectic spacing was noted. The solidification model which includes the kinetic effect has been developed, although the effect appears to be negligible under present experimental conditions. A spacing limit might also occur due to the result of heat flow problems. Heat flow out of the ceramic is difficult to control, often causing radial and not axial growth. This behavior is exaggerated in the presence of impurities. Thus, higher purity powders should always be used. Higher purity samples, in addition to yielding a more microstructurally uniform ceramic, also showed increased directionality. In the future, the kinetic model needs to be examined in more detail, and further research needs to be accomplished in the area of molten ceramics. Once better system constants are in place, the kinetic model will give a better indication of the behavior in the alumina-zirconia system. DOE

APPLICATION OF QUATERNARY PHASE DIAGRAMS TO COMPOUND SEMICONDUCTOR PROCESSING
R. Sinclair 1994 20 p
(Contract DE-FG03-84ER-45085)
(DE95-001813; DOE/ER-45085/T2) Avail: CASI HC A03/MF A01

Isobaric, isothermal phase diagrams are a molar representation of condensed phases in equilibrium with each other at a fixed temperature, pressure, and composition. Since three or four elements are usually involved at a fabricated interface in a semiconductor device, knowledge of the appropriate ternary or quaternary phase diagram is important for optimizing the processing parameters and designing long term stability of devices. While the use of phase diagrams is well-established in the fields of metallurgy, ceramics and mineralogy, only recently have phase diagrams been employed to provide a framework for understanding thin film reactions on a substrate, encountered in semiconductor processing. Even though there are many examples of applications of ternary phase diagrams in the semiconductor literature (for instance, metallization of GaAs, the use of refractory metal silicides for metallization layers in VLSI devices and oxidation of III-V compounds), the same is not true for quaternary phase diagrams. To date, the only application is oxidation of mercury cadmium telluride. This lack of examples is not warranted, as four elements are often involved at a critical interface in compound semiconductor processing and devices. This paper reports on the progress made to remedy this situation by considering the application of quaternary phase diagrams to understanding and predicting the behavior of II-VI thin film interfaces in photovoltaic devices under annealing conditions. Moreover, for the first time, solid solubility is taken into account for quaternary phase diagrams of semiconductor systems. DOE

TAILORING SUSPENSION FLOW FOR THE GELCASTING OF OXIDE AND NONOXIDE CERAMICS
O. O. Omatete and A. Bleier 1994 8 p Presented at the Spring Meeting of the Materials Research Society, San Francisco, CA, 4-8 Apr. 1994
(Contract DE-AC05-84OR-21400)
(DE95-001351; CONF-940411-55) Avail: CASI HC A02/MF A01

Gelcasting is a forming process in which a concentrated slurry of ceramic powders suspended in a solution of organic monomers is polymerized to form a green body of the powder held in a polymeric gel. The process is suited to the production of near-net-shape complex parts. The slurry should contain high solids loading (approximately 50 vol%) in order to minimize shrinkage and distortion during drying and, thus, to produce a relatively dense green body that facilitates sintering of the green part to full density. To produce complex-shaped bodies, however, the slurry has to be fluid at the high solids loading, to flow, and to fill complex-shaped molds. Consequently, there is the need to study the rheology of the gelcasting slurries of typical ceramic powders in order to understand the factors that govern the flow and pourability of these slurries. The rheology of gelcasting slurries of concentrated (30 - 60vol%) alumina, zirconia, silicon nitride, and sialon powders with isoelectric points varying between pH 5 and 9, was studied by measuring the viscosity and yield stress as functions of pH. Typically, the rheology is non-Newtonian. The lowest values of viscosity and yield stress that permit the highest solids loading were obtained at high and low pH values, where the powders are colloidally stable, far from the isoelectric points. This relationship applies whether or not a polymer dispersant is present. The acrylamide monomer which is used in gelcasting slurries, lowers these non-Newtonian properties permitting the preparation of more concentrated slurries. Fluid and pourable gelcasting slurries of each powder had apparent viscosities and yield stresses less than 2.0 Pa(center dot)s and 50 Pa, respectively. DOE

(Contract N00014-82-K-0612)
(AD-A279125) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Immobilized enzymes are used in bioreactors and biosensors. Current methods for immobilizing enzymes include adsorption or covalent attachment to a support, microencapsulation, and entrapment within a membrane/film or gel. The ideal enzyme immobilization method would (1) employ mild chemical conditions; (2) allow for large quantities of enzyme to be immobilized; (3) provide a large surface area for enzyme/substrate contact within a small total volume; (4) minimize barriers to mass transport of substrate and product; and (5) provide a chemically and mechanically robust system. This report describes a new method for enzyme immobilization that satisfies all of these criteria. We have developed a template-based synthetic method that yields hollow polymeric microcapsules of uniform diameter and length. These microcapsules are arranged in a high density array in which the individual capsules protrude from a surface like the bristles of a brush. We have developed procedures for filling these microcapsules with high concentrations of enzymes. The enzyme-loaded microcapsule arrays function as enzymatic bioreactors in both aqueous solution and organic solvents. DTIC

MAGNETIC PROPERTIES OF THE THREE-DIMENSIONAL ISING MODEL WITH AN INTERFACE AMORPHIZATION
A. Benyoussef (Mohammed V Univ., Rabat, Morocco.), Y. ElAmraoui (Mohammed V Univ., Rabat, Morocco.), A. ElKenz (Mohammed V Univ., Rabat, Morocco.), and M. Saber (Mohammed V Univ., Rabat, Morocco.) Sep. 1993 20 p
(DE94-628992; IC-93/304) Avail: CASI HC A03/MF A01 (US Sales Only)

A three-dimensional ferromagnetic Ising model with an interface amorphization is investigated with the use of the effective field theory. Phase diagrams and reduced magnetization curves of interface and bulks are studied. We obtain a number of characteristic behaviour such as the possibility of the reentrant phenomena and a large depression of interface magnetization. DOE

ALIGNED BISMUTH, STRONTIUM, CALCIUM CUPRATE COATINGS ON POLYCRYSTALLINE SUBSTRATES Patent
Louis E. Toth, inventor (to Navy) and J. R. Spann, inventor (to Navy) 20 Sep. 1994 11 p Filed 21 Dec. 1993
(AD-D016512; US-Patent-5,348,937; US-Patent-Appl-SN-170962; US-Patent-Class-505-238) Avail: US Patent and Trademark Office

An article comprises an oriented thick film superconducting coating on a polycrystalline substrate. The coating includes at least two highly oriented platelet components of Bi(a)Sr(b)Ca(c)Cu(d)O(x) (BSCCO) wherein, in one component, a is 2, b is 2, c is 1, d is 2, and x is 8 and, in another component, a is 2, b is 2, c is 0, d is 1, and x is approximately 6, oriented such that said BSCCO platelets are essentially parallel to said substrate. Suitable polycrystalline substrates are MgO and alumina and mullite. DTIC

COST-EFFECTIVE CERAMICS PROGRAM IN THE UNITED STATES
R. B. Schulz (Department of Energy, Washington, DC.) and D. R. Johnson 1994 6 p Presented at the 5th International Symposium on Ceramic Materials and Components for Engines, Shanghai, China, 29 May - 1 Jun. 1994
(Contract DE-AC05-84OR-21400)
(DE95-001425; CONF-9405187-3) Avail: CASI HC A02/MF A01

The 5-year Cost-Effective Ceramics for Heat Engines program began in 1993. This effort reflects the realization that the problems with reliability of structural ceramics have been largely overcome, but the high cost of structural ceramics has limited their use in commercial applications. The technical causes of high cost were identified, and a technical plan developed. The work elements in the program include the following: economic cost modeling, ceramic machining, powder synthesis, alternative forming and densification processes, yield improvement, standards development, and low-expansion ceramics. CERAMIC TECHNOLOGY FOR ADVANCED HEAT ENGINES
D. R. Johnson and R. B. Schulz (Department of Energy, Washington, DC.) 1994 9 p Presented at the Science and Technology Materials Conference, Greensboro, NC, 27-29 Oct. 1993
(Contract DE-AC05-84OR-21400)
(DE95-000950; CONF-9310328-3) Avail: CASI HC A02/MF A01

The Ceramic Technology Project was initiated in 1983 for the purpose of developing highly reliable structural ceramics for applications in advanced heat engines, such as automotive gas turbines and advanced heavy duty diesel engines. The reliability problem was determined to be a result of uncontrolled populations of processing flaws in the brittle, flaw-sensitive materials, along with microstructural features, such as grain boundary phases, that contribute to time dependent strength reduction in service at high temperatures. The approaches taken to develop high reliability ceramics included the development of tougher materials with greater tolerance to microstructural flaws, the development of advanced processing technology to minimize the size and number of flaws, and the development of mechanical testing methodology and the characterization of time dependent mechanical behavior, leading to a life prediction methodology for structural ceramics. The reliability goals of the program were largely met by 1993, but commercial implementation of ceramic engine components has been delayed by the high cost of the components. A new effort in Cost Effective Ceramics for Heat Engines was initiated in 1993 and is expected to develop the manufacturing technology leading to an order of magnitude cost reduction. The program has been planned for a five year period. DOE

Thermal and oxidative stability, deposition and foaming techniques were developed for predicting the performance of candidate 4 cSt lubricants, polyphenyl ether (PPE), C-ether and other experimental fluids for use in advanced aircraft turbine engines. A novel sealed tube test was developed to study the rate of reaction in both liquid and vapor phase using only microliter quantities of the lubricants. Blending agents and/or diluents were used to improve the low temperature properties and high temperature oxidative stability of PPE. In-line magnetic wear sensors were evaluated as condition monitoring devices for oil systems with sensitivity well below 5 micrometers. Microfiltration effect on wear was investigated with the results showing effective reduction in secondary wear. HP-DSC analysis technique was limited as an oxidative stability screening device for PPE but was effective in demonstrating differences among various PPE formulations. The tribological behavior of high temperature fluids was evaluated and compared in the boundary lubrication regime using various steel and ceramic specimens. A sliding three-ball-on-disk wear test device was developed for reducing sample size, controlling scar geometry and determining lubricant consumption rate and tribochemistry. The effect of soft and hard solid particulates on the fatigue and wear lives of rolling elements was investigated using a recently developed three-ball rolling test. DTIC

ANALYSIS OF COST: COMBUSTION FLAME CVD DIAMOND DEPOSITION Quarterly Report No. 1
1994 21 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-93-C-2044)
(AD-A279153) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

IBIS Associates has developed its predictive spreadsheet model of combustion flame chemical vapor deposition (CVD) diamond film fabrication. This report explains the assumptions for combustion flame deposition theory, and shows preliminary results of the economics of this CVD diamond process. For this report and the results contained herein, it is assumed that the transport theory model which predicts growth rates in the CVD diamond technical cost model closely predicts actual growth rates for the combustion flame technology and that the input values for variables such as the gas flow rate and substrate diameter are physically achievable. With this assumption as the basis for cost estimation, the cost of producing 1,000 planarized polycrystalline diamond wafer at one millimeter thick is estimated in the long run to be $73 per square centimeter for the combustion flame technology. ROBOTIC PAINT STRIPPING CELL Final Technical Report, 1 Apr. 1986 - 1 Aug. 1993
James Lukemeyer Nov. 1993 208 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract F33615-86-C-5044)
(AD-A279158; WL-TR-93-8029) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The purpose of this work has been to develop a robotic system for stripping paint from F-16 aircraft using non-chemical means and to integrate the system at Ogden Air Logistics Center (OO-ALC). The Robotic Paint Stripping Cell (RPSC) is an automation system consisting chiefly of two large robots developed for removal of paint from fighter size aircraft and aircraft components using the plastic media blast (PMB) process. The system was installed at Hill AFB in the Plastic Media Blast Booth at building 220 and put into production use by the Air Force in September 1992. The technical effort on this project resulted in the development of an automated system incorporating two robots of unique kinematic design especially suited for paint stripping and general surface processing of fighter-size aircraft. A more consistent paint stripping quality is achievable with the sensor-based, computer-controlled robotic plastic media blast system than is possible using manual methods. The sensor-based controls are used for all F-16 substrate materials, including graphite-epoxy composites. The RPSC is a fully automated plastic media blast paint stripping system, providing improvement of operator health and safety conditions by removing them from the blast environment. DTIC

EPOXY LINING FOR SHIPBOARD PIPING SYSTEMS Interim Report
Robert F. Brady, Jr. and James D. Adkins 30 Sep. 1994 30 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A286228; NRL/MR/6120-94-7629) Avail: CASI HC A03

The Naval Research Laboratory has developed an epoxy lining to prevent corrosion and erosion of copper-nickel pipe. Before being approved for use aboard ship, the lining was tested in the laboratory for resistance to chemicals found in sanitary systems and tested in a simulated ship piping system for application viscosity and hardening time. Commercially-available linings were also tested but found to be deficient in one or more critical properties. Entrained air in the applied coating is avoided more easily by control of application parameters than by the use of air-releasing additives in the lining. The process used to install the lining is described in detail. The Navy now uses this lining to restore corroded or eroded ship piping systems rapidly without lengthy disruption of shipboard operations. This technology has been shown to be a proven inexpensive alternative to replacement of pipe. DTIC

STRUCTURAL PERFORMANCE OF CYLINDRICAL PRESSURE HOUSINGS OF DIFFERENT CERAMIC COMPOSITIONS UNDER EXTERNAL PRESSURE LOADING. PART 4: SILICON CARBIDE PARTICULATE REINFORCED ALUMINA CERAMIC Final Technical Report
Ramon R. Kurchubasche, Richard P. Johnson, Jerry D. Stachiw, and Thomas A. Johnson Dec. 1993 134 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(NR Proj. S03-97)
(AD-A286299; NRAD-TR-1594-Pt-4) Avail: CASI HC A07

Twelve 12-inch-OD by 18-inch-long by 0.412-inch-thick silicon-carbide particulate reinforced alumina-ceramic cylinders were fabricated, assembled, and pressure tested to determine their suitability for use as external pressure-resistant housings for underwater applications. The material, designated 90-X-089, is made by Lanxide Corporation (Newark, DE) by a proprietary directed metal oxidation (DIMOX(TM)) process. The primary advantages of this material are its high compressive strength, high elastic modulus, high fracture toughness, low specific gravity, and ability to be cast in near net shapes, eliminating the need for expensive diamond grinding. Pressure test results are presented along with strain gage data, cyclic fatigue-life data, and acoustic emissions. Conclusions regarding the suitability of the material for application to pressure housings for underwater applications are presented along with a comparison to WESGO's AL-600 96-percent alumina ceramic, which was chosen as a base of comparison for various advanced materials being evaluated under the same program. Recommendations for design implementation, nondestructive evaluation, and further research are made. DTIC

THE ROLE OF POINT DEFECTS AND DEFECT COMPLEXES IN SILICON DEVICE PROCESSING
B. Sopori and T. Y. Tan Aug. 1994 171 p Presented at the 2nd Workshop on Role of Point Defects/defect Complexes in Silicon Device Fabrication, Breckenridge, CO, 24-26 Aug. 1992
(Contract DE-AC36-83CH-10093)
(DE94-011876; NREL/TP-413-7064; CONF-9208175-Summ) Avail: CASI HC A08/MF A02

This report is a summary of a workshop hold on August 24-26, 1992. Session 1 of the conference discussed characteristics of various commercial photovoltaic silicon substrates, the nature of impurities and defects in them, and how they are related to the material growth. Session 2 on point defects reviewed the capabilities of theoretical approaches to determine equilibrium structure of defects in the silicon lattice arising from transitional metal impurities and hydrogen. Session 3 was devoted to a discussion of the surface photovoltaic method for characterizing bulk wafer lifetimes, and to detailed studies on the effectiveness of various gettering operations on reducing the deleterious effects of transition metals. Papers presented at the conference are also included in this summary report. DOE

DEMONSTRATION OF MULTIFUNCTIONAL DNBM CORROSION INHIBITORS IN PROTECTIVE COATINGS FOR NAVAL AIR/WEAPON SYSTEMS Final Report, Sep. 1989 - Jul. 1992
L. J. Bailin Dec. 1993 50 p
(Contract N62269-89-C-0258)
(AD-A285869; LMSC-P000457; NAWCADWAR-60-94128) Avail: CASI HC A03/MF A01

The corrosion protective properties of multifunctional DNBM salts (quaternary ammonium dichromate, nitrate, borate, and molybdate) have been demonstrated on high-strength steel and aluminum alloys found in prototype aerospace weapon systems. The 100% DNBM mixture added to MIL-P-23377 epoxy-polyamide, minus strontium chromate inhibitor, on bare 7075-T6 aluminum alloy resisted 1000 h ASTM B-117 salt spray. However, the coatings were not resistant to hydraulic fluid immersion at the higher concentrations required for the corrosion inhibition. Microencapsulation of the reactive DNBM mixture was adopted as a means to prevent this susceptibility, as well as the destructive oxidation of the hydroxyl groups in the epoxy resin during cure. In the scale-up operation, approximately 20 gallons of DNBM weighing 64 kg (141 lb) was prepared from the four starting quarternary salts synthesized in a chemical process pilot plant. The salts were mixed by dissolving in toluene. Following removal of solvent, the resultant dark-brown liquid, approximating molasses in viscosity, was microencapsulated by the following method: The DNBM was dispersed to form an oil-in-water emulsion in an aqueous colloidal solution of low-viscosity, high-purity methyl cellulose using a Gifford-Wood homogenizer, followed by spray drying in an Anhydro spray dryer. The maximum practicable payload was 75% DNBM. DTIC

HIGH TEMPERATURE POLYMER FOR SECOND ORDER NONLINEAR OPTICS FOR PHOTONIC MATERIALS
Hilary S. Lackritz 12 May 1994 15 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-92-J-1415)
(AD-A279309) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

We are examining a variety of novel high temperature stable polymers as new materials for second order nonlinear optical (NLO) and photorefractive devices. Current polymers have sufficient optical signal generated by available chromophores, but are not practical for device applications because of limitations in the temporal stability of the dopant orientation in the polymer caused by poor thermal stability of the host. This is a novel approach for developing a new class of photonic materials with superior thermal and temporal stability and is the first attempt to design a second order NLO polymer with controllable, tailorable local physical and electrical properties. A second, equally important goal is to understand the basic polymer physics controlling the thermal and temporal stability of the optical chromophore orientation. This will determine not only the overall efficiency of the materials for device applications, but will generate substantial information about mobility in high temperature stable polymer systems. MATERIALS SUPPORT FOR THE DEVELOPMENT OF HIGH TEMPERATURE ADVANCED FURNACES (HITAF): A COMPARISON OF SELECTED MECHANICAL PROPERTIES FOR THREE SIC-BASED CERAMICS
K. Breder and V. J. Tennery 1994 12 p Presented at the 10th Annual Coal Preparation, Utilization and Environmental Control Contractors Conference, Pittsburgh, PA, 18-21 Jul. 1994
(Contract DE-AC05-84OR-21400)
(DE94-017752; CONF-940780-4) Avail: CASI HC A03/MF A01

The purpose of this project is to compare structural ceramic materials proposed for use in the air heater of a coal fired high temperature advanced furnace (HITAF) for power generation. The work will provide necessary initial strength and statistical material parameters for design of a prototype system. Two teams are currently funded by Pittsburgh Energy Technology Center (PETC) under the Combustion 2000 program to develop such a system. One team is led by the United Technologies Research Corporation, and consists of UTC Turbo Power and Marine Division, Bechtel, Oak Ridge National Laboratory (ORNL) and a Joint Venture of Physical Sciences Inc. (PSI) Technologies, Reaction Engineering International (REI) and University of North Dakota Energy & Environmental Research Center (UNDEERC); the other team is led by Foster Wheeler Development Corporation, and members are AiResearch Division of Allied Signal Aerospace Systems & Equipment, Research Cottrell, TRW, General Electric and Bechtel. TOWARDS TAILORED INTERPHASE FORMATION UTILIZING SURFACE-BOUND BENZYLSULFONIUM SALTS AS CATIONIC INITIATORS
John A. McGowen and Lon J. Mathias 15 Nov. 1994 3 p
(Contract N00014-89-J-1225)
(AD-A286461; TR-78) Avail: CASI HC A01/MF A01

This study centers on designed composite interphases based on using polymer synthesis to chemically link initiating groups to fiber surfaces, promote radial growth of the interphase out from the surface, and finally initiate matrix cure. The approach is based on tailoring interphase formation before matrix cure, and should help to develop very strong interactions between the composite components. Novel benzylsulfonium salts have been synthesized which possess an alkyl ether tether tied to a reactive trialkoxysilane moiety capable of covalently bonding with glass surfaces. Recently it has been shown that benzylic sulfonium salts can be excellent latent initiators for epoxy resins, vinyl ethers, and spiro orthocarbonates or bicyclo orthoesters. Here we report the coupling of these sulfonium salts with high surface area silica gel as a model for glass fibers. High surface area silica was chosen due to the high loadings achievable, allowing for more facile characterization of the degree of functionalization. The surface-bound sulfonium salts will be used to initiate the cationic polymerization of various resins based on epoxy functionality. Characterization of the surface-bound sulfonium salts on silica, cure kinetics of unbound and surface-bound initiator with a commercial epoxy resin system and preliminary composite formation with glass fibers will be presented. STRENGTH TESTING OF TI-VAPOR-COATED SILICON NITRIDE BRAZE JOINTS
M. L. Santella 1994 21 p Presented at the American Society of Mechanical Engineers' Winter Annual Meeting, Chicago, IL, 9-11 Nov. 1994
(Contract DE-AC05-84OR-21400)
(DE94-017858; CONF-941142-18) Avail: CASI HC A03/MF A01

Sintered silicon nitride was vacuum brazed to itself at 1130C with a Au-25Ni-25Pd wt % filler metal. Wetting was obtained by coating the Si3N4 surfaces with titanium prior to brazing by electron beam evaporation. The brazed joints were virtually free of porosity. Metallographic analysis showed that Ti reacted with the Si3N4, to form a TiN reaction layer during brazing. Small amounts of Si and Ti dissolved in the filler metal layers but they did not appear to influence the mechanical properties of the braze layer. Flexure bars were made from the brazed coupons and tested at room temperature, 600C, 700C, and 800C in air. At 700C and below, fracture of the test bars occurred in the Si3N4, either near the brazed surfaces or at some distance into the monolithic material. The measured strength of joint specimens decreased slightly with increasing test temperature, and generally exceeded the intrinsic braze filler metal strength in this temperature range. It was also found that lapping the Si3N4, prior to Ti coating reduced the number of near-surface flaws and produced joints with higher average strength and lower scatter than those left in a ground condition. Specimens tested at 800C had very low strengths, and this behavior was related to the microstructure at the brazed Si3N4 surfaces. DOE

MEASUREMENT OF RESIDUAL STRESSES ON CERAMIC MATERIALS WITH HIGH SPATIAL RESOLUTION
K. J. Kozaczek, C. O. Ruud (Pennsylvania State Univ., University Park, PA.), and J. D. Fitting (Pennsylvania State Univ., University Park, PA.) 1993 6 p Presented at the 6th International Symposium on Nondestructive Characterization of Materials, Oahu, HI, 7-11 Jun. 1993
(Contract DE-AC05-84OR-21400)
(DE94-017889; CONF-930685-1) Avail: CASI HC A02/MF A01

A fast x-ray diffraction technique has been developed for measuring the residual stresses with high spatial resolution in ceramic materials. This resolution is limited by the mean size of grains and the radiation type. The effective diffraction elastic constants were experimentally determined for alumina as (E/l+(nu))(sub (1016)) = 200 GPa. The accuracy of XRD measurement of residual stresses with the spatial resolution of 170 micro m and precision +/- 15 MPa was verified experimentally by strain gauge measurements. The stress field around a singular Kovar pin brazed to alumina was asymmetric with high tangential stresses in the vicinity of the pin decreasing with the distance from the pin. DOE

ABSORPTION OF WATER AND LUBRICATING OILS INTO POROUS NYLON
P. A. Bertrand 10 Jan. 1995 20 p Sponsored in cooperation with NASA. Goddard Space Flight Center and Space and Missile Systems Center
(NASA-CR-197344; NAS 1.26:197344; ATR-95(5826)-1) Avail: CASI HC A03/MF A01

Oil and water absorption from air into sintered porous nylon can be described by infiltration into the pores of the material. This process can be modeled by a diffusion-like mechanism. For water absorption, we find a formal diffusion coefficient of 1.5 x 10(exp -4)sq cm/min when the nylon is initially dry. The diffusion coefficient is 4 x 10(exp -6)sq cm/min when the nylon is oil-impregnated prior to air exposure. In a 52% RH atmosphere, dry nylon absorbs 3% w/w water, and oil-impregnated nylon absorbs 0.6% w/w water. For oil absorption there are three steps: (1) surface absorption and infiltration into (2) larger and (3) smaller pores. Surface absorption is too fast to be measured in these experiments. The diffusion coefficient for the second step is 6 x 10(exp -4)sq cm/min for SRG-60 oil into dry nylon and 4 x 10(exp -4)sq cm/min for air-equilibrated nylon. The diffusion coefficient for the third step is about 1 x 10(exp -6)sq cm/min for both cases. The total amount of oil absorbed is 31% w/w. The interaction between water and nylon is not as strong as that between water and cotton-phenolic: oil can replace water, and only a small amount of water can enter previously oil-impregnated nylon. DETERMINATION OF THE COMPLEX ELASTIC MODULI OF MATERIALS USING A FREE-FREE BAR TECHNIQUE M.S. Thesis
David L. Bartlett Mar. 1994 214 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A279861) Avail: CASI HC A10

The objective of this research is to investigate the dynamic elastic properties of materials and their temperature and frequency dependence using an acoustic resonance based method. In this technique, the torsional, flexural, and/or longitudinal vibrational modes of a 'free-free' bar are selectively excited and tracked as a function of temperature. The resonance frequency of the torsional model is used to obtain the dynamic shear modulus. The dynamic Young's modulus is obtained from either the resonance frequency of the flexural or longitudinal mode of the bar. The quality factor, Q, of each mode is measured to obtain the damping properties of the material. A phase-locked-loop (PLL) is used to track the resonance frequency as a function of changing temperature for the particular vibrational model selected. Using this technique, the storage modulus and loss tangent may be obtained in a continuous fashion. Materials tested in this thesis include: Polyurethane PR-1592, a common sonar encapsulant, Polymethyl Methacrylate (PMMA) or plexiglass, and Polycarbonate. This research encompasses the theory, accuracy, limitations and applications of this measurement technique. DTIC

CHARACTERIZATION AND PERFORMANCE OF DLC FILMS SYNTHESIZED BY PLASMA AND ION BEAM TECHNIQUES
K. C. Walter, H. Kung, T. Levine, P. Kodali, B. P. Wood, D. J. Rej, M. Nastasi, Jarkko Koskinen (Technical Research Centre of Finland, Espoo, Finland.), and J.-P. Hirvonen 1994 18 p Presented at the 4th International Conference on Plasma Surface Engineering, Garmisch-Partenkirchen, Germany, 19-23 Sep. 1994
(Contract W-7405-eng-36)
(DE94-018287; LA-UR-94-2821; CONF-9409196-1) Avail: CASI HC A03/MF A01

Diamond-like carbon (DLC) films have been deposited on dissimilar substrates using three different deposition processes. Two well-studied methods, employing cathodic arcs and RF-plasma self-bias, have been used. These two processes differ in that cathodic arc processes use gas pressures less than 1 mtorr and deposit atomic ions with energies less than 100 eV, while RF-plasma self-bias processes use gas pressures greater than 1 mtorr and deposit molecular ions with energies greater than 100 eV. In addition, DLC films have been deposited using a new plasma-based, pulsed-bias process. The pulsed-bias process uses gas pressures greater than 1 mtorr and deposits molecular ions with energies greater than 1,000 eV. Both the self-bias and pulsed-bias processes utilized hydrocarbon gases as the carbon source. Cathodic arc processes generally rely on the arc between two graphite electrodes as the carbon source. Deposited films from all three processes have been characterized using ion backscattering techniques, Elastic Recoil Spectrometry (ERS), Transmission Electron Microscopy (TEM) and Selected Area Diffraction (SAD). Films deposited using the cathodic arc process are virtually hydrogen free while the self-bias and pulse-bias films contain up to 40% hydrogen. TEM results indicated the films are homogeneous and amorphous. The hardness, elastic modulus, coefficient of friction and wear rate of the films are also reported. DOE

(DE95-002740; LA-UR-94-3552; CONF-9407145-1) Avail: CASI HC A02/MF A01

This paper summarizes our cumulative work on neutron reflectivity studies of polystyrene-poly(vinyl-2-pyridine) (PS-PVP) and polystyrenepolyethylene oxide (PS-PEO) adsorbed at a quartz-solvent interface. Deuterated toluene was chosen as the solvent since it is a good solvent for PS and a poor one for either of the other two blocks. In this case, the polystyrene dangles into the solvent while the other block acts as an anchor. The neutron reflectivity studies reveal that the form of the polymer density profile normal to the substrate may be varied from an extended 'brush' to a condensed 'mushroom' conformation by manipulating the ratio of the molecular weights of the two blocks. In addition, we present new data on the PS-PEO system in a poor solvent, deuterated cyclohexane, under conditions of shear flow in Poiseuille geometry. We find that when the PS-PEO diblock is absorbed from cyclohexane and is allowed to relax, the PS chain takes on a 'mushroom' conformation. However, when the shear is applied, the layer shear thickens due to the PS chains extended to nearly twice their original lengths. DOE

We have compared the metallic evaporation channels from metastable (Ag(sub X=5,7,11)AgI(sub Y=1-4))(+) clusters in the 1st FFR of a double focussing mass spectrometer with that of the corresponding pure metallic clusters, (Ag(sub X=5,7,11))(+). It is found that the presence of the polar AgI molecules increases the rate of silver monomer evaporation relative to that of silver dimer evaporation. Using thermodynamic expressions for the heat of evaporation of the different evaporation processes and assuming the absence of reverse activation energies, an expression for the difference between the activation energy of silver monomer and dimer evaporation is derived. It is shown that dipole/induced-dipole forces resulting from the presence of AgI polar molecules lead to an enhancement of silver monomer evaporation if the polarizability of the pure metallic cluster ions increases with the number of Jellium electrons. Our theoretical calculations of the static polarizabilities of (Ag(sub x))(+) using time dependent density functional theory within the local density approximation, shows a smooth increase in the polarizabilities with the number of the Jellium electrons in these clusters. Finally, we observe that the enhancement of Ag monomer evaporation per AgI added is smaller for clusters with even number of AgI molecules than with odd numbers. This was proposed to result from the contribution of configurations with dipole 'pairing' of the AgI molecules in clusters with even number of AgI molecules. Dipole pairing would decrease the average dipole/induced-dipole interaction between the AgI molecules and the metallic part of these 'mixed' clusters. DTIC

HEAT TRANSFER, FOULING, AND COMBUSTION OF SUPERCRITICAL FUELS Final Report, 15 Aug. 1992 - 31 Mar. 1994

L. D. Chen 28 Apr. 1994 67 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract F49620-92-J-0462)
(AD-A279906; AFOSR-94-0321TR) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The specific objectives of the project were to investigate the dynamics of the vortex and flame interaction in jet diffusion flames and the transport phenomena associated with the injection of supercritical fluids into a sub-critical environment. The vortex-flame interaction in a near-laminar jet diffusion flame was quantified by a planar visualization and the vortex formation in a transitional jet diffusion flame by a line visualization. The measured vortex crossing frequency in transitional jet diffusion flames was used to verify the time-dependent diffusion flame calculations. The experiments also quantified the spray length in two different ambient environments composed of dissimilar species. The mixture pseudo-critical states were calculated for the conditions examined. The spray length, the calculated mixture pseudo-critical states, along with images of instantaneous light scattering and shadowgraph showed that the mixing of dense fluids dictated the spread of mist-like droplets and vapor-phase injector fluid. The supercritical sprays also exhibited flashing-like atomization as concluded from the experiments. Further investigation on the mixing in the super-critical sprays was suggested. DTIC

HIGH PRESSURE WINDOWED CHAMBER BURNED RATE DETERMINATION OF LIQUID PROPELLANT XM46 Final Report, Oct. 1991 - Sep. 1993
W. F. McBratney and J. A. Vanderhoff Jun. 1994 32 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A283770; ARL-TR-442) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

A high-pressure windowed strand burner has been used to obtain burning rates for XM46 over the pressure range from 10 to 300 MPa. Burn rates for the liquid XM46 were erratic due to surface irregularities. This burning surface variable was minimized by gelling; two different gelling agents were used. The burn rate (r) vs. pressure (p) can be adequately expressed by an exponential of the form r = Apn. A definite pressure break occurs around 70 MPa for gelled XM46. For pressures below about 70 MPa, n is approximately 0.2 and for pressures between 70 and 300 MPa, the two different gelling agents gave n values of 1.0 and 1.2. DTIC

DEGRADATION OF AROMATIC HYDROCARBONS IN AN AQUIFER DURING A FIELD EXPERIMENT DEMONSTRATING THE FEASIBILITY OF REMEDIATION BY NATURAL ATTENUATION Final Technical Report, Oct. 1989 - Sep. 1992
Thomas B. Stauffer, Christopher P. Antworth, Riki G. Young, William G. MacIntyre, and J. M. Boggs Apr. 1994 155 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A283809; AL/EQ-TR-1993-0007) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The purpose of this experiment was to perform a controlled field experiment, involving the injection of several aromatic hydrocarbons and a nonreactive tracer into an uncontaminated aquifer. By monitoring the plume development of these solutes, and by measuring a number of physical and chemical characteristics of the aquifer, this study was designed to provide data on those properties which significantly control the propagation of dissolved contaminants in groundwater systems. A secondary objective was to measure the in situ degradation rates of the selected organic compounds. The disappearance and transformation of the organic solutes during this experiment demonstrated that natural degradation processes were able to effectively reduce these levels of dissolved organic contaminants in a reasonable time frame. This represents the most important result of this field study, since active remediation would not be needed in situations where natural degradation rates were sufficient to reduce contaminant concentrations to safe levels. The monetary and environmental cost savings of allowing natural biological restoration of the residual contaminants are potentially enormous. It appears that this study is the first field experiment to prove conclusively that hydrocarbon solute losses were due to chemical degradation rather than physical losses. DTIC

BIOCONVERSION OF COAL DERIVED SYNTHESIS GAS TO LIQUID FUELS
M. K. Jain, R. M. Worden, and H. Grethlein 15 Apr. 1994 8 p
(Contract DE-AC22-92PC-92117)
(DE94-017381; DOE/PC-92117/T8) Avail: CASI HC A02/MF A01

The overall objective of the project is to develop an integrated two-stage fermentation process for conversion of coal-derived synthesis gas to a mixture of alcohols. This is achieved in two steps. In the first steps, Butyribacterium methylotrophicum converts carbon monoxide (CO) to butyric and acetic acids. Subsequent fermentation of the acids by Clostridium acetobutylicum leads to the production of butanol and ethanol. DOE

THE HOT FRAGMENT CONDUCTIVE IGNITION TEST FOR SCREENING LOVA PROPELLANTS
T. T. Nguyen and P. Berry Mar. 1994 12 p
(AD-A284259; MRL-TN-661; DODA-AR-008-629) Avail: CASI HC A03/MF A01

The Hot Fragment Conductive Ignition (HFCI) Test was set up to determine the relative ignitability of propellant grains in response to hot fragments of different masses heated to different temperatures. The minimum temperature at which the propellant ignites gives a measure of the ignitability of the propellant. The test is a rapid screening to evaluate the vulnerability of propellant to an external aggressive stimulus such as spall attack. A number of different types of propellants including CAB/RDX propellants, nitrocellulose (NC)-based propellants and HTPB/RDX composite propellants were tested. The HTPB/RDX and NC-based propellants were found to be more vulnerable than the CAB/RDX propellants. DTIC

EFFECT OF PROPANE-AIR ON NGVs AND VEHICLE FUELING STATIONS Topical Report, 1 Jan. - 1 Oct. 1993
W. E. Liss and D. S. Moulton Jun. 1994 181 p
(Contract GRI-5086-293-1848)
(PB94-210085; SWRI-3178-4.8; GRI-94/0158) Avail: CASI HC A09/MF A02

Propane-air (P/A) peakshaving is an important element of peak-load management for some U.S. gas utilities. P/A is used as a supplemental energy medium with natural gas and has been shown to operate satisfactorily in most natural gas applications. The propane levels injected are compatible with the pressures (under 200 psig) and temperatures (over 40 F) found in utility distribution networks. However, P/A can create problems for natural gas vehicles (NGVs) operating on compressed gas as well as NGV fueling stations. This report contains information on P/A peakshaving and its compatibility with NGV's by documenting condensation impacts at nine conditions--i.e., three propane levels and three temperatures. These data portray the depressurization of a vehicle tank, an area selected because it illustrates NGV operation and can discriminate between acceptable and potentially non-acceptable operating points. These analyses show, not surprisingly, a correlation exists between propane level, ambient temperature, and condensation. NTIS

AGING TESTS OF ETHYLENE CONTAMINATED ARGON/ETHANE
M. Atac and G. Bauer (Massachusetts Inst. of Tech., Cambridge, MA.) 22 Sep. 1994 15 p
(Contract DE-AC02-76CH-03000)
(DE95-002526; FNAL/C-94/340-E) Avail: CASI HC A03/MF A01

We report on aging tests of argon/ethane gas with a minor (1800 ppM) component of ethylene. The measurements were first conducted with the addition of alcohol to test the suppression of aging by this additive, with exposure up to approximately 1.5 C/cm. Tests have included: a proportional tube with ethanol, another with isopropyl alcohol, and for comparison a tube has also been run with ethanol and argon/ethane from CDF's old (ethylene-free) ethane supply. The aging test with ethanol showed no difference between the ethylene-free and the ethylene tube. Furthermore, raw aging rates of argon/ethane and argon/ethane/ethylene were measured by exposing tubes without the addition of alcohol to about 0.1 C/cm. Again, no significant difference was observed. In conclusion, we see no evidence that ethylene contamination up to 1800 ppM has any adverse effect on wire aging. However, this level of ethylene does seem to significantly suppress the gas gain. DOE

DEVELOPMENT OF AN ADVANCED JP-8 FUEL Final Report, Aug. 1990 - Jan. 1993
Tedd B. Biddle Dec. 1993 45 p
(Contract F33615-90-C-2051)
(AD-A285583; PWA-FR23047; WL-TR-94-2033) Avail: CASI HC A03/MF A01

Technical effort was directed at increasing the design limit of current JP-8 fuel from 325 F (163 C) to 425 F (218 C) at the fuel nozzle. The objective was to accomplish this near-term thermal stability goal solely through the use of a fuel soluble additive package. JP-Thermally stable fuel was considered the thermal stability target since it has the high-temperature properties sought from the significantly more economical JP-8 + 100 formulation. The additives were evaluated in an additive-free Jet A considered typical of fuel most likely to be encountered in the field. DuPont JFA-5, currently the only accepted thermally stability improving additive, was considered state of the art and used as a bench mark. Additive manufacturers were surveyed and solicited for candidate additives that had potential for improving fuel thermal oxidative stability. Test methods were developed and/or refined for use in screening additives. Using the Hot Liquid Process Simulator (HLPS) in conjunction with a LECO Carbon Determinator, 152 additives were screened. Additive performance was ranked based on surface carbon and differential pressure. Additional screening was performed using the Isothermal Corrosion Oxidation Test (ICOT). Additives screened included oxygen, sulfur, and nitrogen-type antioxidants; dispersants; detergents; metal deactivators; antifoulants; and proprietary thermal stability improvers. Twenty-seven experimental blends comprised of various additive combinations were tested. Five baseline fuels were evaluated. DTIC

THE CARNOL PROCESS FOR METHANOL PRODUCTION AND UTILIZATION WITH REDUCED CO2 EMISSIONS
M. Steinberg and Yuanji Dong Oct. 1993 22 p Presented at the International Conference on Global Climate Change: Science, Policy and Mitigation Strategies, Phoenix, AZ, 5-8 Apr. 1994
(Contract DE-AC02-76CH-00016)
(DE94-016808; BNL-60575; CONF-940426-3) Avail: CASI HC A03/MF A01

A first order comparative mass and energy analysis is made of alternative processes for the production and utilization of methanol. Conventional reforming of natural gas with steam and CO2 indicates a yield of approximately 1 mol of methanol per mol of methane and a net emission of 1 mol of CO2 per mol of methanol. Three new processes called - Carnol I, Carnol II and Carnol III utilize CO2 as a feedstock in conjunction with hydrogen produced from the thermal decomposition of methane can reduce CO2 emission compared to the conventional process by 35%, 88%, and 100% respectively while reducing methanol production by 11%, 35%, and 39% respectively. The carbon from methane decomposition can be sequestered or sold as a commodity. The methanol can be used in the transportation sector as an alternative efficient fuel. A preliminary economic estimate indicates the equivalent cost for reduction of CO2 to be less than estimates for removal, recovery, and disposal of CO2 from power plant stack gas. The Carnol process leverages the CO2 reduction both from central fossil fuel fired power plants and the transportation sector. The Carnol process assists in the reduction of CO2 emission from an otherwise impossible collection of CO2 from highly dispersed heat engine and small scale fuel users. DOE

A LOW ENERGY CONTINUOUS REACTOR SEPARATOR FOR THE PRODUCTION OF ETHANOL FROM CORN GRITS/STARCH AND BIOMASS STREAMS Quarterly Report No. 2, 1 Aug. - 15 Oct. 1994
M. Clark Dale 1994 22 p
(Contract DE-FG01-94CE-15594)
(DE95-002256; DOE/CE-15594/T2) Avail: CASI HC A03/MF A01

This project is an attempt to develop and demonstrate an improved reactor for the production of ethanol from starch and ligno-cellulosic streams. Bio-Process Innovations holds a patent on this reactor technology, and is directing the project. A Continuous Stirred Reactor Separator (CSRS) is being built on a pilot plant scale for testing at a small Iowa ethanol plant (Permeate Refining) while bench scale tests on the reactor system are being performed at Purdue University. The CSRS unit combines several operations within the confines of the reactor vessel: (1) complex carbohydrates are reduced to simple sugars by enzymatic breakdown; (2) sugars are converted to ethanol by yeast or bacteria; and (3) the ethanol is separated by a stripping gas stream. The ethanol is removed from the stripping gas in an absorber, and then taken to an extractive distillation column. This unit should allow concentrated feeds to be converted to ethanol, and the use of bottoms recycle will be extensively tested to establish the limits of minimizing net bottoms water production leaving the plant. During the first quarter, a flocculant yeast was selected, a xylose fermenting yeast strain selected, and some experiments on no-cook starch conversion to ethanol completed. During the last (second) quarter, the authors have tested the effect of bottoms water recirculation on the reactor performance, the performance of the lab scale unit on molasses, and done some work on biomass conversion to ethanol. Recent work on the decomposition of hexahydro-1,3,5-trinitro-s-triazine (RDX) and octahydro-1,3,5,7-tetranitro-1,3,5,7-tetrazocine (HMX), utilizing simultaneous thermogravimetric modulated beam mass spectrometry (STMBMS), has shown that they undergo significant decomposition in both the solid and liquid phases. Previous studies have determined the mechanisms of several reaction pathways that control the decomposition of these materials. This paper presents a summary of this previous work and how the results can be applied to developing models to predict the response of energetic materials in cookoff situations. DOE

In support of the manufacture and storage of paste explosives, several membrane materials were evaluated as barriers to permeation. The permeation was quantified to evaluate leakage of the fluids from paste explosives during long-term storage. Four permeants were evaluated, though not every permeant was evaluated with every material. Mass uptake measurements were made during prolonged submersion of the materials in the permeants. Equilibrium amount absorbed and rate of absorption were used to calculate the diffusivity, and permeability of the given solvent/polymer pair. Permeabilities through membrane materials were judged using a cutoff of 10(exp -10) mol/s/m above which permeation was unacceptably high. None of the materials tested was suitable for containing TCB at 125 deg C. Additionally, PFA was unacceptable at 75 C. Viton showed unacceptable permeation in ENP, but FEP and PFA were effective barriers for ENP. No significant differences were found in the permeabilities of different thicknesses of FEP and PFA with ENP. All of the materials (including the elastomer Kalrez) tested with both the explosive FEFO and the propellant EDNP were adequate barriers to their permeation. Polyethylene is unsuitable for contact with FEFO at elevated temperatures because of chemical reactions that occur with the polymer. DOE

AN INITIAL ASSESSMENT OF THE PROPERTIES OF 2,5-DIPICRYL-1,3,4-OXADIAZOLE: A SECONDARY EXPLOSIVE WITH HIGH THERMAL STABILITY
Michael Kony, Lucianna Montelli, and Daniel J. Whelan Oct. 1993 14 p
(MRL-TR-93-16; AR-008-281) Copyright Avail: Issuing Activity (DSTO Materials Research Lab., PO Box 50, Ascot Vale, Victoria 3032, Australia)

The preparation and properties, including hazard assessment, of 2,5-dipicryl-1,3,4-ozadiazole (DPO) are discussed and compared to HNS. DPO was observed to have high thermal stability and was found to be less hazardous to electrostatic spark than HNS. Rotter impact sensitiveness data showed DPO to be more impact sensitive than HNS. Consequently DPO is not suitable, without desensitization, for use below the shutter, in the explosive train of fuzes. High specific surface area DPO (14.5 sq m/g) was prepared and its performance in small slapper detonator devices was evaluated and compared to that of HNS. Both DPO and HNS, at similar surface areas, were found to have similar shock initiation energies. Author

DIFFUSE REFLECTANCE SPECTRA OF ENERGETIC MATERIAL
Rodney A. J. Borg Sep. 1994 24 p
(DSTO-TR-0065; AR-008-928) Copyright Avail: Issuing Activity (DSTO Aeronautical and Maritime Research Lab., GPO Box 4331, Melbourne, Victoria 3001, Australia)

The diffuse reflectance spectra of pure, solid HNS, TNT, HMX, RDX and PETN have been recorded. These spectra reveal that all of the high explosives (HE) have strong absorption profiles in the UV region of the spectrum and much weaker absorption in the visible/near infrared. The influence of particle size on the diffuse reflectance spectra has also been investigated. Reducing the particle size leads to a blue shift of the diffuse reflectance spectrum. The strength of the absorption of the pure HE and the UV region obscures details in the absorption profile. Dilution of the HE with a strong reflector was used to reduce the magnitude of the absorption and allow the UV absorption to be revealed in detail. Chemical interaction between the diluent and HE reduces the general applicability of this approach. Author

NUMERICAL STUDY OF CONTAMINANT EFFECTS ON COMBUSTION OF HYDROGEN, ETHANE, AND METHANE IN AIR
H. T. Lai (NYMA, Inc., Brook Park, OH.) and S. R. Thomas Feb. 1995 14 p Presented at the Sixth International Aerospace Plane and Hypersonics Conference, Chattanooga, TN, 10-14 Apr. 1995; sponsored by AIAA
(Contract NAS3-27186; RTOP 505-62-52)
(NASA-TM-106844; E-9409; NAS 1.15:106844; AIAA Paper 95-6097)
Avail: CASI HC A03/MF A01

A numerical study was performed to assess the effects of vitiated air on the chemical kinetics of hydrogen, ethane, and methane combustion with air. A series of calculations in static reacting systems was performed, where the initial temperature was specified and reactions occurred at constant pressure. Three different types of test flow contaminants were considered: NP, H2O, and a combustion of H2O and CO2. These contaminants are present in the test flows of facilities used for hypersonic propulsion testing. The results were computed using a detailed reaction mechanism and are presented in terms of ignition and reaction times. Calculations were made for a wide range of contaminant concentrations, temperatures and pressures. The results indicate a pronounced kinetic effect over a range of temperatures, especially with NO contamination and, to a lesser degree, with H2O contamination. In all cases studied, CO2 remained kinetically inert, but had a thermodynamic effect on results by acting as a third body. The largest effect is observed with combustion using hydrogen fuel, less effect is seen with combustion of ethane, and little effect of contaminants is shown with methane combustion. Author

LAUNCH SAFETY, TOXICITY, AND ENVIRONMENTAL EFFECTS OF THE HIGH PERFORMANCE OXIDIZER CLF(5)
J. A. Syage 31 Mar. 1994 33 p
(Contract F04701-93-C-0094)
(AD-A286095; TR-94(4231)-4; SMC-TR-94-38) Avail: CASI HC A03/MF A01

An assessment is presented for the human toxicity, environmental, and ecological consequences resulting from accidental releases of ClF5 liquid propellant. Various accident scenarios are considered involving instantaneous releases of 2000 kg of propellant. Plume dispersion profiles were calculated using the AFTOX code for typical climate conditions at Vandenberg Air Force Base (VAFB). For a ground-based cold spill or combustion, the area exceeding long-term human exposure levels is less than 1 km square, and the exposure time is well under an hour (typically several minutes). The area exceeding short-term exposure levels is probably less than 0.1 km square. The toxic hazard is is likely to be less important than the combustion and fire hazard to on-site personnel. Plant life damage would be limited to temporary leaf burns and some defoliation within 300 meters of the spill site. Sea life would be unaffected in the vicinity of

VAFB. Further study should consider the complex interplay of aerosol dynamics and heterogeneous chemistry with propellant and by-products as well as ground deposition of propellant and by-products by gaseous (dry) and aerosol (wet) fallout. The stratospheric impact of a post-launch explosion is small. Fluorine is not very destructive of the ozone due to the extreme stability of the sink molecule HF. The amount of chlorine compound resulting from a combustion of 2000 kg of ClF5 is not large enough to have a significant effect on the stratosphere, even on a transient scale. Routine solid rocket motor firings present a far greater chlorine load on the atmosphere than does any credible ClF5 accident scenario. DTIC

MICROGRAVITY: TEACHER'S GUIDE WITH ACTIVITIES FOR PHYSICAL SCIENCE

Gregory L. Vogt (National Aeronautics and Space Administration. Lyndon B. Johnson Space Center, Houston, TX.), Michael J. Wargo, and Carla B. Rosenberg, ed. Jan. 1995 78 p

(NASA-EG-103; NAS 1.19/4:103) Avail: CASI HC A05/MF A01

This guide is an educational tool for teachers of grades 5 through 12. It is an introduction to microgravity and its application to spaceborne laboratory experiments. Specific payloads and missions are mentioned with limited detail, including Spacelab, the International Microgravity Laboratory, and the United States Microgravity Laboratory. Activities for students demonstrate chemistry, mathematics, and physics applications of microgravity. Activity objectives include: modeling how satellites orbit Earth; demonstrating that free fall eliminates the local effects of gravity; measuring the acceleration environments created by different motions; using a plasma sheet to observe acceleration forces that are experienced on board a space vehicle; demonstrating how mass can be measured in microgravity; feeling how inertia affects acceleration; observing the gravity-driven fluid flow that is caused by differences in solution density; studying surface tension and the fluid flows caused by differences in surface tension; illustrating the effects of gravity on the burning rate of candles; observing candle flame properties in free fall; measuring the contact angle of a fluid; illustrating the effects of gravity and surface tension on fiber pulling; observing crystal growth phenomena in a 1-g environment; investigating temperature effects on crystal growth; and observing crystal nucleation and growth rate during directional solidification. Each activity includes a background section, procedure, and follow-up questions. CASI

GRAVITATIONAL EFFECTS ON THE DEVELOPMENT OF WELD-POOL AND SOLIDIFICATION MICROSTRUCTURES

L. A. Boatner, S. A. David, and G. Workman (Alabama Univ., Huntsville, AL.) 1994 8 p Presented at the Microgravity Materials Science Conference, Huntsville, AL, 24-25 May 1994

(Contract DE-AC05-84OR-21400)

(DE94-017772; CONF-9405220-1) Avail: CASI HC A02/MF A01

This research effort has as its objective the development of a quantitative understanding of the effects of both low- and high-g environments on the solidification microstructures and morphologies that are produced in alloy single crystals during a variety of melting and solidification processes. The overall goal of the effort is to delineate the nature of the roles played by natural convection, surface-tension-driven convection, and mass transport effects due to interactions associated with various heating methods that are used to form melt pools in practical, commercially important alloy systems. The experimental and theoretical investigations comprising this effort encompass the study of configurations in which stationary heat sources are employed as well as melt pools formed by moving heat sources like those frequently used in fusion-welding processes. SOLIDIFICATION MODELING OF A SPIRAL CASTING TO DETERMINE MATERIAL FLUIDITY

S. Ahuja, H. M. Domanus, R. C. Schmitt, L. Chuzhoy (Caterpillar Tractor Co., Peoria, IL.), and J. V. Grabel (Caterpillar Tractor Co., Peoria, IL.) Feb. 1994 11 p

(Contract W-31-109-eng-38)

(DE94-018930; ANL-94/11) Avail: CASI HC A03/MF A01

In casting, fluidity is the measure of the distance a metal can flow in a channel before being stopped by solidification. During mold filling, the metal loses heat to the surrounding mold, thereby cooling and becoming more viscous until the leading portion solidifies and no further flow is possible. A coupled heat-transfer and fluid-flow modeling of a spiral, involving the use of thermophysical properties to determine material fluidity, has been conducted. Fluidity experiments were performed by Caterpillar; several spiral test castings were poured. Simulations of these experiments utilized the Casting Process Simulator (CaPS) software developed at Argonne National Laboratory. Two types of spiral geometries with different assumptions were considered: (1) a two-dimensional laterally stretched spiral; and (2) a three-dimensional lateral spiral. The computed extent of mold filling is in good agreement with the experimental results. Time required by the metal/gas interface to attain specific positions in the spiral arm also compared favorably with the experimental results. The influence of process variables, especially pour time, is discussed. The CaPS software has been used as a computational tool to investigate the validity of the dimensionality assumptions and to evaluate the ability of CaPS to model fluidity adequately. DOE

NUMERICAL CONTROLLED POLISHING PROGRAM, CONTINUED FORCED WEAR AND PART CORRECTION EXPERIMENTS

Philip R. Hannah, Robert D. Day, Douglas J. Hatch, and E. Ray McClure 1994 5 p Presented at the American Society for Precision Engineers (ASPE) Conference, Cincinnati, OH, 2-7 Oct. 1994

(Contract W-7405-eng-36)

(DE94-018084; LA-UR-94-2716; CONF-9410185-1-Extd-Abst) Avail: CASI HC A01/MF A01

This abstract reports the near completion of the first phase of this program. It is the aim of this program to provide the operator of a N/C diamond turning machine or N/C grinding machine (jig grinder) with the wear characteristics necessary to achieve uniform material removal. The second phase of this program addresses a different problem, although solving this problem is highly dependent on the results of the first phase. Diamond turned, or any lathe turned surface, exhibits regular tool marks due to the tool passing over the surface being cut. Changes in depth of cut, feed rate and work rpm will change the character of these grooves, but will not eliminate them. Optical surfaces produced by this process exhibit increased scattering as the light wavelength decreases limiting their use; at least for optical purposes, to IR and some visible applications. Utilizing wear information gathered in the first part of this program we will attempt to reduce these residual tool marks by polishing. The polishing of diamond turned surfaces is not new. Diamond turned metal surfaces, especially in electroless nickel and high phosphorus nickel electroplate have been polished to improve their scatter characteristics. What we believe is unique is the use of a spherical wheel, rotating on axis and being moved over the part in a prescribed manner by numerical control. Over the past year we have made some major changes in our polishing methods and procedures. We have listed below these changes, as a refresher for the reader as to our previous procedures. These changes will be addressed in the body of the text. DOE

THE DEVELOPMENT AND EVALUATION OF WATER-MIST FIRE EXTINGUISHING SYSTEMS
D. G. Beason and K. J. Staggs Aug. 1994 3 p
(Contract W-7405-eng-48)
(DE94-019019; UCRL-ID-118068) Avail: CASI HC A01/MF A01

Fire protection for underfloor space is primarily provided by Halon 1301 which has proven to be very effective. However, due to the link between halons and the possible depletion of the stratospheric ozone layer, plans have been implemented to eventually phase out Halon 1301 and 1211. In September 1987 the Montreal Protocol concerning chlorofluorocarbons (CFC) and halons was signed by the United States, the European Economic Community, and 23 other nations. The Montreal Protocol calls for freezing halon production at 1986 levels. Because the majority of underfloor fire protection at Lawrence Livermore National Laboratory (LLNL), as well as other Department of Energy (DOE) sites, is either Halon 1301 or sprinklers, some other means of suppression will have to be developed and verified. The potential loss to facilities housing computer or control rooms damaged by underfloor fires can be extreme. These losses would not only include hardware and software replacement costs, but also lost computing and control capability. Here at LLNL technical research in a facility could be severely affected. Recent studies conducted by the Fire Research Discipline of the Special Projects Division have shown that severe fires fueled by cable insulation can develop within as little as a 6-in-high underfloor space (even with mechanical ventilation shut off). Studies also show that conventional sprinklers may not be effective in preventing this destruction. Therefore, we are investigating the water-mist fire extinguishing system as an alternative to Halon 1301 and sprinklers. DOE

TRAINING SIMULANT FOR HALON 1211 PORTABLE EXTINGUISHERS
Joseph T. Leonard, R. Burns (Hughes Associates, Inc., Columbia, MD.), P. Jones (Hughes Associates, Inc., Columbia, MD.), and R. Ouellette (Hughes Associates, Inc., Columbia, MD.) 8 Sep. 1994 31 p
(AD-A285403; NRL/MR/6180-94-7615) Avail: CASI HC A03/MF A01

The Standard Navy portable Halon 1211 extinguisher can be modified to provide an environmentally acceptable simulant for training. The modifications include replacement of the Halon 1211 with pressurized water as the fire fighting agent and insertion of a full cone spray nozzle in the horn of the extinguisher to form a suitable spray pattern. The modified extinguisher has the same physical appearance and discharge characteristics (time, reach, etc.) as the standard Halon 1211 extinguisher and weighs just two pounds less. Since it uses water as the fire fighting agent, the training simulant has zero Ozone Depletion Potential, zero Global Warming Potential and is non-toxic. Also, there is a potential savings of $160,000-$190,000 per year, based on a usage of 20,000 lbs/year of Halon 1211 for training. DTIC

(PB94-215555; STF20-A93218) Avail: Issuing Activity

Simulation of the injection molding process is a helpful way for the engineers who work with plastics processing. By simulation, they will get some important parameters which sometimes are highly necessary for the mold design and processing. Thus, the engineers will save much time to do experiments for the parameters. Two simulation programs are used in this report, namely CADMOULD and CADMOULD MEFISTO which are designed by Institut fur Kunststoffverarbeitung (IKV) in Aachen, W. Germany. CADMOULD works with 2-D geometry and is specialized for rheological, thermal and mechanical calculation. It is installed on a personal computer, while CADMOULD MEFISTO works in 3-D and is installed on a VAX 8530 computer at SINTEF. A PC version of this program is also available. This report deals with CADMOULD and CADMOULD MEFISTO. The construction of flow lines, balancing of sprue system, the optimizing of injection time, and gate(s) optimizing are mainly included. NTIS

(PB95-128674; NISTIR-5305) Avail: CASI HC A03/MF A01

FIREDOC is the on-line bibliographic database which reflects the holdings (published reports, journal articles, conference proceedings, books, and audiovisual items) of the Fire Research Information Services (FRIS) at the Building and Fire Research Laboratory (BFRL), National Institute of Standards and Technology (NIST). This manual provides step-by-step procedures for entering and exiting the database via telecommunication lines, as well as a number of techniques for searching the database and processing the results of the searches. This Third Edition is necessitated by the change to a UNIX platform. The new computer allows for faster response time if searching via a modem and, in addition, offers internet accessibility. FIREDOC may be used with personal computers, using DOS or Windows, or with Macintosh computers and workstations. A new section on how to access Internet is included, and one on how to obtain the references of interest to you. Appendix F: Quick Guide to Getting Started will be useful to both modem and Internet users. NTIS

SUMMARIES OF BFRL FIRE RESEARCH IN-HOUSE PROJECTS AND GRANTS, 1994
Nora H. Jason, ed. Oct. 1994 213 p See also report for 1993, PB94-121050
(PB95-130845; NISTIR-5504) Avail: CASI HC A10/MF A03

This report describes the fire research projects performed in the Buildings and Fire Research Laboratory (BFRL) and under its extramural grants program during Fiscal Year 1993. Included are research performed both with funds appropriated to the BFRL Fire Research Program and under contract to outside organizations. The BFRL Fire Research Program has directed its efforts under four program thrusts. The in-house priority projects, extramural grants, and externally-funded efforts thus form an integrated, focussed ensemble. This publication is organized along those lines: (1) Performance-based Fire Standards; (2) Fire Safe Materials and Products; (3) Advanced Fire Sensing and Suppression; (4) Large/Industrial Fires. For the convenience of the reader, an alphabetical listing of all grants is contained in the Part 2.0. NTIS

DETERMINATION OF LAYER MODULI FROM FALLING WEIGHT DEFLECTOMETER MEASUREMENTS
A. Ruotoistenmaeki 1994 71 p
(PB95-129748; VTT/RN-1552) Copyright Avail: Issuing Activity (National Technical Information Service (NTIS))

Back calculation programs are used for evaluation of pavement layer moduli from falling weight deflectometer (FWD) measurements. A comparison of two programs with different calculation methods, Modulus and Elmod, is made using deflection data derived from 43 SHRP-LTPP (Strategic Highway Research Program, Long-Term Pavement Performance) test sections. Critical strains were calculated using the linear program (BISAR) with layer moduli from the Modulus program as input and with the Elmod program. It was found that calculated strains from the two programs agree very well, even though the calculated moduli are quite different. Calculated strains from FWD loading were compared with measured strains under moving wheel load at Virttaa test site. The differences between the two are most likely due to differences in the loading conditions and in the method of analysis. NTIS

SAFETY ISSUES IN HIGH SPEED MACHINING [SUURNOPEUSJYRSINNAEN TYOETURVALLISUUS]

31 May 1994 74 p In FINNISH Prepared in cooperation with Technical Research Centre of Finland, Espoo, Finland
(PB95-127411; KPT-4/94) Avail: Issuing Activity (National Technical Information Service (NTIS))

There are several risks related to High-Speed Milling, but they have not been systematically determined or studied so far. Increased loads by high centrifugal forces may result in dramatic hazards. Flying tools or fragments from a tool with high kinetic energy may damage surrounding people, machines and devices. In the project, mechanical risks were evaluated, theoretic values for kinetic energies of rotating tools were calculated, possible damages of the flying objects were determined and terms to eliminate the risks were considered. The noise levels of the High-Speed Machining center owned by the Helsinki University of Technology (HUT) and the Technical Research Center of Finland (VTT) in practical machining situation were measured and the results were compared to those after basic preventive measures were taken. NEW CONCEPTS FOR REFRIGERANT LEAK DETECTION AND MIXTURE MEASUREMENT

F. C. Chen, S. L. Allman, and C. H. Chen 1993 8 p Presented at the 1993 International CCFC and Halon Alternatives Conference, Washington, DC, 20-22 Oct. 1993
(Contract DE-AC05-84OR-21400)
(DE94-018967; CONF-9310191-3) Avail: CASI HC A02/MF A01

Since the discovery that chlorofluorocarbons (CFC's) destroy the ozone layer, the need to reduce the release of these refrigerants into the environment has become critical. A total ban of ozone-depleting CFC's is expected within a few years, and hydrofluorocarbons (HFC's) and fluorocarbons (FC's) and their mixtures are expected to be used during a transition period. Several HFC and FC refrigerants are currently being considered as CFC substitutes. The electronic refrigerant leak detectors currently being considered as CFC substitutes. The electronic refrigerant leak detectors currently on the market were developed to detect CFC's and are not as sensitive to HFC's. Although incremental improvement can be made to these devices to detect HFC's, they often lead to increased false signals. Also, there is no simple device available to measure the composition of a refrigerant mixture. The authors present two new concepts to aid in the development of two portable instruments that can be used for HFC leak detection and for quantitative measurement of refrigerant mixture compositions. The development of simple, easy-to-use portable leak detectors and refrigerant mixture meters is essential to the wide use of alternative refrigerants in industry. DOE

EVALUATION OF STATE-OF-THE-ART HIGH SPEED DELUGE SYSTEMS PRESENTLY IN SERVICE AT VARIOUS US ARMY AMMUNITION PLANTS Final Report, Jan. - Mar. 1993

A. D. Goedeke and G. A. Fadorsen Sep. 1993 72 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract F08635-91-C-0217)
(AD-A279102; WL-TR-93-3510) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

A brief study was made of ultra high speed deluge systems used in Army ammunition plants for fire protection against pyrotechnic and propellant material-type fires/explosions. The evaluation included both fire detectors and fire suppressant devices and technologies. It was found that the technologies being utilized today have not been optimized for the specific fire application. In general, it was found that there is a lack of information on the properties of the fire events themselves that detectors are supposedly designed to respond to. No data exists on spectral irradiances in the IR or UV spectral bands where the current detectors operate. A need exists to determine the sources that may be responsible for detector false alarms. Tests should be conducted on the performance of current systems and on other detection and suppression techniques, notably, machine vision fire detection. It is recommended that field testing of old and new hardware systems be conducted; modifications be made to optimize currently installed systems; a new system capability be developed which better meets the overall threat, performance, and reliability requirements; and a thorough purchase description/performance specification be developed. COMPARISON OF HFC-134a AND THE TERNARY BLEND, SUVA MP39, AS REPLACEMENTS FOR THE REFRIGERANT, CGC-12

Lyn E. Fletcher Sep. 1993 20 p
(MRL-GD-0051; AR-008-273) Copyright Avail: Issuing Activity (DSTO Materials Research Lab., PO Box 50, Ascot Vale, Victoria 3032, Australia)

The refrigerant gas CFC-12 has been widely used in Royal Australian Navy (RAN) equipment. With the Montreal protocol phase-out of this and other ozone depleting substances, alternative refrigerant gases must be identified. These replacements would ideally have the same efficiency as CFC-12, cause no health and safety risks and allow changeover to proceed with minimal costs. This paper reviews the attributes of two refrigerant gases, HFC-134a and Suva MP39, which are being considered by the RAN. Author

OPERATING MANUAL FOR HYBRID THERMOSYPHONS AT THE GAKONA POWER PLANT, ALASKA

F. D. Haynes, Frederick C. Crory, Kurt V. Knuth, and William F. Quinn Mar. 1994 27 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A279068; CRREL-SR-94-3) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

A power plant building was constructed in 1990 at an over-the-horizon radar site in Gakona, Alaska. Since it was built on permafrost, thermal protection between the building and the underlying permafrost was included in the design, which included rigid board insulation and hybrid thermosyphons placed in the gravel fill under the building. Soil temperature is monitored with eight thermistor strings placed under and at the building perimeter. This manual describes the steps that must be taken to ensure foundation stability, including directions on when to use the thermosyphons in the active, mechanical refrigeration mode. A data acquisition system using a computer-controlled datalogger is described. DTIC

SURFACE MICROMACHINED CAPACITIVE TACTILE IMAGE SENSOR Ph.D. Thesis
M. R. Wolffenbuttel 25 Apr. 1994 136 p
(PB95-108031; ISBN-90-6275-967-X) Copyright Avail: Issuing Activity (National Technical Information Service (NTIS))

An overview of the various available sensing principles for tactile images and the strategies for the fabrication of these structures are presented, starting from the earliest elastomer-based structures and concluding with recently presented silicon-based structures with on-chip instrumentation. Some principal aspects in the mechanical functioning of the sensor structure are discussed. The realization of the tactile image sensor with on-chip transistors is discussed, with the focus on the technological feasibilities. The available principles for the read-out of a sensor capacitance to detect the stretching of silicon diaphragms under mechanical pressures is presented. Other circuit elements which are required to interface a digital processor are described, and a series of simulation and measurement results to examine the agreement with the theoretical models are presented. EXTRUDATE SWELL AND EXTRUDATE DISTORTION OF HDPE AS A RESULT OF DIFFERENT DEFORMATION MECHANISMS DURING EXTRUSION THROUGH CAPILLARY DIES
S. Eggen and E. L. Hinrichsen 8 Jun. 1994 31 p
(PB95-110227; STF24-A94039) Avail: Issuing Activity (National Technical Information Service (NTIS))

The effect of varying the die entrance angle and the die length on extrudate swell and on the onset of extrudate distortion in capillary extrusion has been studied. Using theory from the literature, the authors have analyzed the contribution to the total pressure drop from the elongational and shear deformation in the entrance region, and from the capillary pressure drop in the land region of the die. From the contribution of the elongational deformation, they obtained an estimate for the elongational viscosity of the polymer. The same analysis was also used to study the influence of the die geometry on the stick-slip instability. The authors also propose a model for predicting extrudate swell. Input to the model are material parameters obtainable from oscillatoric measurements of the loss and storage modulus and parameters calculated from the geometry of the die. Some of the parameters needed in the model are obtained from a silimar analysis as the one used to derive the elongational properties of the polymer based on the contribution to the pressure drop from the different deformation mechanisms the entrance region. The model includes a fitting parameter that sets the overall scale of the swell. NTIS

FRAME AND EDGE SEAL TECHNOLOGY: A STATE OF THE ART SURVEY
Marit Thyholt, Inger Andresen, Berit Hugdal (Technical Univ. of Norway, Trondheim.), and Oeyvind Aschehoug (Technical Univ. of Norway, Trondheim.) 3 Apr. 1994 64 p
(PB95-110334; STF62-A94004) Avail: CASI HC A04/MF A01

In windows, the glazing is traditionally mounted in an operable or fixed frame, made of wood, metal (steel or aluminum), or PVC. The glazing component in solar collectors and solar walls is also typically mounted in a frame. The purpose of the frame is to protect the vulnerable edge of the glazing and give structural stability, which is especially important in operable windows. Sealed multipane glazings are almost exclusively fabricated with a metal (aluminum or galvanized steel) spacer bar along the edges. New advanced glazings will require new types of frame and edge seal products. As the insulation properties of the glazing itself reach a performance close to that of well-insulated opaque walls, the thermal bridging caused by the spacer bars and the frames will be unacceptable, even for wooden windows. The new glazings will also integrate other functions, which again will influence the design of the frames. There are already quite a few new technological developments in this field. New materials and products for the edge seal and the frame are being developed, and computer calculations gradually take over the manual analysis and laboratory testing of new products. The objective of this IEA Task 18 Case Study is to investigate the influence of the frame and glazing edge seal on the total U-value of a glazing system, to develop improved test and calculation methods, and to design, construct, and test low thermal loss frames for use in advanced glazing applications. ALGEBRAIC SEMANTICS OF MESSAGE SEQUENCE CHARTS
S. Mauw and M. A. Reniers Apr. 1994 53 p
(PB95-110581) Avail: CASI HC A04/MF A01

Message Sequence Charts is a graphical and textual language for the description and specification of the interactions between system components and their environment. The language is standardized by the ITU-TS (the Telecommunication Standardization section of the International Telecommunication Union, the former CCITT). The main area of application for Message Sequence Charts is as an overview specification of the communication behavior of real-time systems, in particular telecommunication switching systems. Message Sequence Charts may be used for requirement specification, interface specification, simulation and validation, test-case specification and documentation of real-time systems. In the paper the authors present a formal semantics of Message Sequence Charts exploiting techniques from process algebra. The semantics is proposed for standardization within the ITU-TS. The authors start with the semantics of the core language of Message Sequence Charts, Basic Message Sequence Charts, and subsequently add other features such as process creation and termination, refinement and timer handling. AN ABSTRACT MODEL OF ROGUE CODE INSERTION INTO RADIO FREQUENCY WIRELESS NETWORKS. THE EFFECTS OF COMPUTER VIRUSES ON THE PROGRAM MANAGEMENT OFFICE Ph.D. Thesis
Christopher V. Feudo Apr. 1994 158 p
(AD-A285759; DSMC-TR-4-94) Avail: CASI HC A08/MF A02

This dissertation demonstrates that inadequately protected wireless LANs are more vulnerable to rogue program attack than traditional LANs. Wireless LANs not only run the same risks as traditional LANs, but they also run additional risks associated with an open transmission medium. Intruders can scan radio waves and, given enough time and resources, intercept, analyze, decipher, and reinsert data into the transmission medium. This dissertation describes the development and instantiation of an abstract model of the rogue code insertion process into a DOS-based wireless communications system using radio frequency (RF) atmospheric signal transmission. The model is general enough to be applied to widely used target environments such as UNIX, Macintosh, and DOS operating systems.

The methodology and three modules, the prober, activator, and trigger modules, to generate rogue code and insert it into a wireless LAN were developed to illustrate the efficacy of the model. Also incorporated into the model are defense measures against remotely introduced rogue programs and a cost-benefit analysis that determined that such defenses for a specific environment were cost-justified. THE DESIGN AND ANALYSIS OF A PHASED ARRAY MICROSTRIP ANTENNA FOR A LOW EARTH ORBIT COMMUNICATION SATELLITE M.S. Thesis
William L. Barfield Jun. 1994 95 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A284791) Avail: CASI HC A05

A Naval Postgraduate School spacecraft design class proposed a multiple beam, phased array, microstrip antenna as part of the preliminary design of a low earth orbit communication satellite. The antenna must provide coverage over the satellite's entire field of view while both uplink and down-link operate simultaneously on the same 1-band frequency. This thesis assesses the feasibility of the antenna proposed in that preliminary design. Design tradeoffs for a microstrip array constrained by both available surface area and a limited mass budget are examined. Two different substrate materials are considered in terms of weight and performance. Microstrip patch theory is applied to array element design and layout and antenna array theory is applied to determine phase and amplitude coefficients. The focus of the design is on obtaining the desired beam shape and orientation, given antenna size constraints. A corporate feed method is discussed and a general design presented. Antenna performance is predicted through the use of a computer model based on Modal Expansion theory and results are plotted in a series of graphs which demonstrate the limitations of the proposed design. EVALUATION OF SUPERCONDUCTING QUANTUM INTERFERENCE DEVICES INTERFACED WITH DIGITAL SIGNAL PROCESSING ELECTRONICS FOR BIOMAGNETIC APPLICATIONS
Pang-Jen Kung, Edward R. Flynn, Roger R. Bracht, and Paul S. Lewis 1994 6 p Presented at the ICSPAT 1994: Signal Procession Applications and Technology, Dallas, TX, 18-21 Oct. 1994
(Contract W-7405-eng-36)
(DE94-016186; LA-UR-94-2620; CONF-9410164-2) Avail: CASI HC A02/MF A01

The performances of a dc-SQUID magnetometer driven by both analog electronics and digital signal processors are investigated and compared for biomagnetic applications. Low-noise (less than 5 microns (Phi) (sub 0)/(radical)Hz at 1 Hz) dc-SQUID's were fabricated by Conductus, Inc. using the all-refractory Nb/Al/Al2O3/Nb process on silicon substrates with on-chip modulation coils and integral washer damping resistors. A second-order gradiometer was magnetically coupled to the input coil of the SQUID to maximize the detected signal strength. The readout of this SQUID gradiometer was achieved using a conventional flux-locked loop (FLL) circuit to provide a linearized voltage output that was proportional to the flux applied to the SQUID. A shielded cylinder was constructed to house the magnetometer to reduce ambient field noise. To realize the digital feedback loop, the analog FLL is replaced except for the preamplifier by a digital signal processing board with dual 16-bit A/D and D/A converters. This approach shows several advantages over the analog scheme including operational flexibility, cost reduction, and possibly, the enhancement of dynamic ranges and slew rates. DOE

MEASUREMENTS OF SHIELDING EFFECTIVENESS AND CAVITY CHARACTERISTICS OF AIRPLANES
D. A. Hill, M. L. Crawford, R. T. Johnk, A. R. Ondrejka, and D. G. Camell Jul. 1994 63 p
(PB94-210051; NISTIR-5023) Avail: CASI HC A04/MF A01

We present measured data for shielding effectiveness, cavity Q, and cavity time constant of three small (twin-engine) airplanes for frequencies from 400 MHz to 18 GHz. Both CW and time-domain measurement methods were used, and the time-domain method yields higher values of cavity Q. Both methods yield Q values below a theoretical upper bound determined by window leakage losses. The measured shielding effectiveness is quite variable, but averages about 15 dB. The measured time constants are also variable and average about 15 ns. This short time constant is a result of the low Q of the aircraft cavities. NTIS

RCS CALCULATION CAPABILITY
1994 52 p
(AD-A286329; MP-94B0000087) Avail: CASI HC A04/MF A01

Over several years, the MITRE Sensor Center has developed and used a capability to calculate the radar cross section (RCS) of complex targets rapidly and accurately. A significant number of projects have been supported with this capability. Capabilities include RCS calculations across frequencies, polarizations, and aspect angles of intercept as well as the calculation of targets over the sea and in various terrain conditions. These capabilities are illustrated and summarized. Derived from text

BEYOND TELECOMMUTING: A NEW PARADIGM FOR THE EFFECT OF TELECOMMUNICATIONS ON TRAVEL
J. S. Niles Sep. 1994 87 p
(DE95-001224; DOE/ER-0626) Avail: CASI HC A05/MF A01

Conventional wisdom about social and economic behavior holds that the use of telecommunications is a natural substitute for transportation. For example, telephone calls can replace travel to meetings, and facsimile or electronic-mail transmission of documents substitutes for courier or postal delivery. The moving of information can replace the moving of people and goods. Vehicle traffic on the national transportation infrastructure can be replaced by digital traffic on what is now called the national information infrastructure (NII). A leading example is telecommuting. This means using telecommunications to replace commuting between home and work. Telecommuting is an optional way of expanding employees' work locations in those circumstances where it yields both improved organizational performance and employee satisfaction. Telecommuting accounts for 7.6 million U.S. workers as of early 1993, up 15% from the 6.6 million counted in 1992. The growth of telecommuting has been strong for the past five years. No one has identified any reasons to suggest that this growth will abate in the forseeable future. DOE

GENERAL PURPOSE SIDELOBE CANCELLER SYSTEM Patent
Frank F. Kretschmer, Jr., inventor (to Navy) and Bernard L. Lewis, inventor

(to Navy) 27 Sep. 1994 7 p Filed 26 Feb. 1979
(AD-D016560; US-Patent-5,351,058; US-Patent-Appl-SN-025952; US-Patent-Class-342-384) Avail: US Patent and Trademark Office

A digital, open-loop, sidelobe canceller system includes an arrangement of auxiliary-channel preprocessing cancellers and a series of main-channel cancellers in which specific cancellers average a different number of samples for cancelling both barrage (continuous) jamming and false-target-repeater jamming, which enter the sidelobes of a radar antenna. The preprocessing cancellers and each of the main-channel cancellers, except the last succeeding main-channel canceller, use long-time averaging (averaging over a large number, n, of samples of the main and auxiliary signals, where n is much greater than 2) for removing barrage jamming from the main signal. The last succeeding main-channel canceller uses short-time averaging (averaging over approximately 2-4 samples) for removing false-target-repeater jamming from the main signal. DTIC

A GROUP COMMUNICATION APPROACH FOR MOBILE COMPUTING MOBILE CHANNEL: AN ISIS TOOL FOR MOBILE SERVICES
Kenjiro Cho and Kenneth P. Birman May 1994 18 p
(Contract N00014-92-J-1866)
(AD-A279785; TR-94-1424) Avail: CASI HC A03/MF A01

This paper examines group communication as an infrastructure to support mobility of users, and presents a simple scheme to support user mobility by means of switching a control point between replicated servers. We describe the design and implementation of a set of tools, called Mobile Channel, for use with the ISIS system. Mobile Channel is based on a combination of the two replication schemes: the primary-backup approach and the state machine approach. Mobile Channel implements a reliable one-to-many FIFO channel, in which a mobile client sees a single reliable server; servers, acting as a state machine, see multicast messages from clients. Migrations of mobile clients are handled as an intentional primary switch, and hand-offs or server failures are completely masked to mobile clients. To achieve high performance, servers are replicated at a sliding-window level. Our scheme provides a simple abstraction of migration, eliminates complicated hand-off protocols, provides fault-tolerance and is implemented within the existing group communication mechanism. DTIC

FACSIMILE TRANSMISSION STANDARDS
Andrew Mudry and Brad Poulin Oct. 1993 51 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A279911; DREO-TN-93-18) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Modern tactical communications systems are becoming increasingly compatible with existing civilian systems. This compatibility allows the military to take advantage of the equipment available commercially and spare the expense of developing costly customized systems. It also increases the interoperability of various communications systems employed by allies involved in multinational operations. Finally, the compatibility allows the military to augment its telecommunications assets with existing commercial equipment and networks during times of conflict. One civilian communication standard that has recently been adopted by the military for tactical communications is that of facsimile. Facsimile is now commonly used on the battlefield for the transmission of tactical maps and situation reports. This technical note examines the requirements for facsimile transmission. An overview of the various facsimile standards are given, followed by a detailed description of the most commonly used standard; CCITT Group III. The Group III specifications are a composite of various CCITT modulation and encoding standards. These consist of V.21, V.27ter, and V.29 modulations, as well as T.4 image encoding standards, and T.30 signalling specifications. Each of these standards is described in the context of facsimile transmissions. A complete description of the handshaking which occurs between the facsimile transmitter and receiver is given. DTIC

BACKSCAT LIDAR SIMULATION VERSION 4.0: TECHNICAL DOCUMENTATION AND USERS GUIDE
David R. Longtin, Michael G. Cheifetz, James R. Jones, and John R. Hummel 10 Jun. 1994 149 p
(Contract F19628-91-C-0093)
(AD-A285851; LTR94-001; PL-TR-94-2170; SR-8) Avail: CASI HC A07/MF A02

SPARTA's BACKSCAT software package simulates the performance of lidars for remote sensing and other atmospheric applications. The package accommodates a wide range of lidar systems, viewing scenarios, and atmospheric conditions, plus it contains a user-friendly menu interface system for specifying input parameters. This report gives technical documentation and a users guide for BACKSCAT Version 4.0. In this effort, comprehensive and versatile signal-to-noise (SNR) performance models have been introduced into BACKSCAT. The SNR models give performance and range accuracy estimates for direct detection and coherent Doppler lidar systems, plus estimates of the wind speed accuracy for coherent Doppler systems. The models contain all important noise sources inherent in the detection process and allow the user to select from built-in detectors, as well as define their own detector specifications. In response to the user community, five water clouds have been added to BACKSCAT and they can be 'clicked-on' automatically as built-in cloud models. BACKSCAT Version 4.0 also contains an auxiliary software package, MABS, that estimates the molecular absorption profile for a lidar wavelength. MABS generates output that can be used in a simulation. Because MABS performs a broadband calculation, it is not intended to be a complete treatment of the molecular absorption problem. Finally, methods of handling the increased size of the BACKSCAT package have been developed. DTIC

APPLICATIONS OF WAVELETS TO RADAR, IMAGING AND RELATED PROBLEMS Final Report, 1 Jul. 1990 - 30 Sep. 1993
Reece Prosser and Dennis M. Healy, Jr. 30 Sep. 1993 14 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Grant AF-AFOSR-0292-90)
(AD-A279909; AFOSR-94-0333TR) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

A primary concern of this study has been waveform design for active inverse problems of acoustic and electromagnetic variety. We developed several useful results in the specific areas of electromagnetic and acoustic bullets, signal design for doppler ultrasound velocimetry and magnetic resonance imaging, and limited data tomography problems arising in medical imaging and in radar. Another area of proposed research involved the construction of maximum likelihood receivers for various novel signal sources, such as those arising in particular wideband acoustic data, and image data from non-euclidean sources. We have developed efficient algorithms in both of these regimes. In particular, we have studied receivers for application to wideband acoustic signal processing in acoustic velocimetry for the dense target environments occurring in Doppler ultrasound problems, and computationally efficient matched filter processor for the sphere. This has direct application to directional data of various forms, with applications from remote sensing problems to quality assurance for CAD/CAM. DTIC

A COLOCATED MAGNETIC LOOP, ELECTRIC DIPOLE ARRAY ANTENNA (PRELIMINARY RESULTS) Interim Report, Oct. 1993 - Sep. 1994
P. L. Overfelt, D. R. Bowling, and D. J. White Sep. 1994 38 p
(AD-A285381; NAWC-WPNS-TP-8212) Avail: CASI HC A03/MF A01

We present a detailed electromagnetic analysis of an electrically small colocated electric dipole and magnetic loop antenna array. This antenna is the simplest example of the Grimes multipole class of antenna arrays. We have determined that since the interaction term between the two elements disappears from the radial complex power, we were able to set the radial reactance to zero by choosing appropriate current magnitudes and phases on the array elements. By driving the two elements in quadrature, we obtained a much increased radiation intensity and directivity as well as increased radiated power. DTIC

GPS-SQUITTER CAPACITY ANALYSIS
Vincent A. Orlando and William H. Harman 20 May 1994 46 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contracts DTFA01-93-Z-02012; F19628-90-C-0002)
(AD-A280037; ATC-214) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

GPS-Squitter is a system concept that merges the capabilities of Automatic Dependent Surveillance (ADS) and the Mode S beacon radar. The result is an integrated concept for seamless surveillance and data link that permits equipped aircraft to participate in ADS and/or beacon ground environments. This concept offers many possibilities for transition from a beacon to an ADS-based environment. This report provides the details of the techniques used to estimate GPS-Squitter surveillance and data link capacity. Surveillance capacity of airborne aircraft is calculated for the omni and six-sector ground stations. Next, the capacity of GPS-Squitter for surface traffic is estimated. The interaction between airborne and surface operations is addressed to show the independence of these systems. Air ground data link capacity for GPS-Squitter is estimated, together with an estimate of the use of the Mode S link to support other ground surveillance and data link activities as well as TCAS operation. The analysis indicates the low transponder occupancy resulting from the total effect of these activities. Low occupancy is a key requirement in avoiding interference with the operation of the current ATCRBS and future Mode S interrogators. DTIC

EMITTER LOCATION VIA KALMAN FILTERING OF SIGNAL TIME DIFFERENCE OF ARRIVAL M.S. Thesis
Richard W. Williamson Sep. 1994 158 p
(AD-A285972) Avail: CASI HC A08/MF A02

A relatively simple time domain method is developed to calculate the time of arrival for radar signals. The error present in the estimate of the time of arrival for a single pulse and a burst of pulses is developed and the effects of SNR, PRF, pulsewidth, and sampling frequency are examined. Time of arrival is used with multiple sensors and the Kalman filter to estimate the location of the emitter. Algorithms estimate the location of an emitter given the Time Difference of Arrival (TDOA) of a single pulse as well as the TDOA of bursts of pulses received as the emitter scans past the receivers. The algorithms were tested on simulated data. DTIC

DIFFRACTION COMPUTATION BY MEANS OF THE METHOD OF EQUIVALENT CURRENTS
L. J. VanEwijk May 1994 45 p
(AD-A285347; FEL-94-B195; TDCK-94-1395) Avail: CASI HC A03/MF A01

In this report the derivation of the Method of Equivalent Currents is given. This method can be used to compute the diffraction of plane waves by edges. A computation of this sort is necessary in addition to a scattering computation using Physical Optics or Geometrical Optics, because these last techniques neglect edge effects by definition. The reason that the Method of Equivalent Currents is chosen is because it is a powerful method, valid at almost all incidence and scattering aspects. Some of the few remaining singularities of the method can be removed in a way described in this report as well. Some interesting comparisons with measured data will be given in order to show the capabilities and shortcomings of the method. DTIC

INNOVATIVE USE OF DSP TECHNOLOGY IN SPACE: FORTE EVENT CLASSIFIER
S. Briles, K. Moore, P. Klingner, D. Neagley, M. Caffrey, K. Henneke, W. Spurgen, P. Blain (Edgerton, Germeshausen and Grier, Inc., Idaho Falls, ID.), and R. Jones 1994 8 p Presented at the ICSPAT 1994: Signal Procession Applications and Technology, Dallas, TX, 18-21 Oct. 1994
(Contract W-7405-eng-36)
(DE94-016086; LA-UR-94-2506; CONF-9410164-5) Avail: CASI HC A02/MF A01

The Fast On-Orbit Recording of Transient Events (FORTE) small satellite will field a digital signal processor (DSP) experiment for the purpose of classifying radio-frequency (RF) transient signals propagating through the earth's ionosphere. Designated the Event Classifier experiment, this DSP experiment uses a single Texas Instruments' SMJ320C30 DSP to execute preprocessing, feature extraction, and classification algorithms on down-converted, digitized, and buffered rf transient signals in the frequency range of 30 to 300 MHz. A radiation-hardened microcontroller monitors DSP- abnormalities and supervises spacecraft command communications. On-orbit evaluation of multiple algorithms is supported by the Event Classifier architecture. Ground-based commands determine the subset and sequence of algorithms executed to classify a captured time series. Conventional neural network classification algorithms will be some of the classification techniques implemented on-board FORTE while in a low-earth orbit. Results of all experiments, after being stored in DSP flash memory, will be transmitted through the spacecraft to ground stations. The Event Classifier is a versatile and fault-tolerant experiment that is an important new space-based application of DSP technology. DOE

FAULT DETECTION TECHNIQUES FOR COMPLEX CABLE SHIELD TOPOLOGIES Final Report, 24 Aug. 1992 - 24 Aug. 1993
Kurt H. Coonrod, Stuart L. Davis, and Donald P. McLemore Sep. 1994 65 p
(Contract F29601-92-C-0109)
(AD-A286632; PL-TR-93-1111) Avail: CASI HC A04/MF A01

This document presents the results of a basic principles study which investigated technical approaches for developing fault detection techniques for use on cables with complex shielding topologies. The study was limited to those approaches which could realistically be implemented on a fielded cable, i.e., approaches which would require partial disassembly of a cable were not pursued. The general approach used was to start with present transfer impedance measurement techniques and modify their use to achieve the best possible measurement range. An alternative test approach, similar to a sniffer type test, was also investigated. DTIC

LOW-COST CONICAL ULTRA-WIDEBAND ANTENNA Final Report, May - Jun. 1994
Eric E. Funk and Stephen E. Saddow Nov. 1994 17 p
(AD-A286569; ARL-TR-302) Avail: CASI HC A03/MF A01

One of the necessary pieces of equipment needed for ultra-wideband (UWB) radio effects measurements is a suitable UWB field probe and radiating antenna. The conical monopole antenna (CMA) is an easy-to-fabricate, inexpensive, and useful UWB device that can be used for both of these applications. In this report we present information that should allow both antenna designers and users to quickly assemble a custom CMA to meet their design goals. A subjective explanation of the theory of operation is presented along with analytical expressions that predict the radiated and received pulse shapes. Experimental results are presented to verify the CMA theory of operation; these results also serve as an example of how UWB radiation can be monitored with a CMA during field measurements. DTIC

REAL-DATA TESTS OF A SINGLE-DOPPLER RADAR ASSIMILATION SYSTEM
Thomas Nehrkorn, James Hegarty, and Thomas M. Hamill 30 Jun. 1994 55 p
(Contract F19628-91-C-0011)
(AD-A286638; PL-TR-94-2199; SR-5) Avail: CASI HC A04/MF A01

Real data tests of a single-Doppler radar data assimilation and forecast system have been conducted for a Florida sea breeze case. The system consists of a hydrostatic mesoscale model used for prediction of the preconvective boundary layer, an objective analysis that combines model first guess fields with radar derived horizontal winds, a thermodynamic retrieval scheme that obtains temperature information from the three-dimensional wind field and its temporal evolution, and a Newtonian nudging scheme for forcing the model forecast to closer agreement with the analysis. As was found in earlier experiments with simulated data, assimilation using Newtonian nudging benefits from temperature data in addition to wind data. The thermodynamic retrieval technique was successful in retrieving a horizontal temperature gradient from the radar-derived wind fields that, when assimilated into the model, led to a significantly improved forecast of the seabreeze strength and position. The requirement for highly survivable communications (HSC) for essential command functions in military operations does not need any justification. The ability to communicate under extreme jamming levels and adverse propagation conditions, including high altitude nuclear events, is a very important requirement. There are also many natural disaster related requirements that also need such highly survivable communications. The prevalent and in a sense classical, approach to provide highly assured connectivity can be summarized as follows: Take a particular propagation medium and try to obtain the ultimate performance from it. There are many examples of this philosophy some successful, most not. Our approach, on the other hand, is to use complementary multi-media or mixed-media where communication links utilizing essentially commercial-off-the-shelf (COTS) equipment are integrated using packet radio (PR) techniques. There is also, in our view, an even more fundamental, recently discovered consideration why the expectation of continuous incremental refinement of a system using a given single media may be be achievable. This is derived from the theory of 'deterministic uncertainty' or more popularly known as 'theory of CHAOS', systems whose state space behavior has fractal characteristics. We will elaborate on this novel argument. Complementary multi-media approach has been the focus for all HSC communications activities at STC since 1982. The original STC studies and prototypes were in response to requirements of broadcasting (i.e., one-way transmission) information. A high frequency (HF)/meteorburst (MB) system was developed/prototyped/tested demonstrating the cost effectiveness of the approach. These results are reviewed. More recently, in 1992 STC has completed the development/test of an Open Systems Interconnection (OSI) HF packet radio protocol as no such open or non-proprietary protocol exists. This protocol has been fully tested, documented and made available to all NATO nations/industries. These extensive results show that significant improvements in throughput of up to many times are obtained. A similar development for an OSI MB protocol has also been completed and combined with the HF protocol to obtain an OSI HF/MB link layer protocol with unique properties for HSC networks. Description of these protocols and the relevant results are presented. The conclusion is that, HSC networks using standard COTS transceivers/modems with OSI PRO protocols can provide highly survivable connectivity, by providing the most important ingredient of survivability, media diversity. QoS DRIVEN ROUTING IN PACKET SWITCHED NETWORKS OF MULTIPLE TRANSMISSION MEDIA
C. Tamvaclis *In* AGARD, Multiple Mechanism Propagation Paths (MMPPs): Their Characterisation and Influence on System Design Jul. 1994 9 p (For primary document see N95-20921 06-32)
Copyright Avail: CASI HC A02/MF A04

This paper discusses the application of Quality of Service (QoS) driven routing on packet-swtiched, heterogeneous networks. It is assumed that the network makes use of multiple transmission media of different types including narrowband radio based media such as those used in military tactical and emergency networks, e.g. ECCM SATCOM, HF radio, etc. A critical problem in the operation of such networks is the volatile performance of the transmission media, compounded by the fact that each transmission medium may respond differently to stress conditions. QoS driven routing provides an effective way to handle transmission media performance fluctuations and optimizing the use of all the available communication resources. QoS driven routing means that packet routes are selected according to a global optimization criterion that takes into account not only network connectivity, but also the application QoS requirements, and the currently available QoS from the network links. A routing architecture is described for implementing QoS driven routing on a connectionless internetwork of multiple transmission media. This architecture is based on the use of civilian networking standards and it is implementable using commercial off-the-shelf equipment. Author

This paper describes the work being carried out to realize a robust digital radio communications system, operational over the frequency range 2-200MHz, which will utilize the existence of multiple mechanism propagation paths (MMPP'S) in order to maximize link-availability. The system incorporates a substantial element of PC-based Digital Signal Processing (DSP). This work is essentially a unification of several areas of ongoing research within the Hull-Lancaster Communications Research Group (HLCRG) on the application of PC and DSP technology in radio system design. Modelling codes exist for many of the propagation mechanisms which may prevail in the frequency range of approximately 2 to 200MHz and many of the models are embodied in CCIR recommendations. Within the past few years, a number of simulation codes have been developed for use within various projects carried out by the Hull-Lancaster Communications Research Group (HLCRG). The proposed paper will describe current work aimed at bringing together the various models and simulation codes in order to produce a realistic simulation of the multiple mechanism propagation path. The multiple mechanisms under consideration conventionally include groundware, ionospheric skywave, sporadic E, ducting and the various scatter modes. In addition, recent work carried out by the HLCRG has revealed that tropospheric reflection may be responsible for stable propagation which is usable in the frequency range 30 to 70MHz for short (up to 400km) over the horizon paths. The development of a propagation model for this mechanism will be included in the presentation. Author

ADAPTIVE ERROR-CONTROL SCHEME FOR 2-200 MHz MULTIPLE-MECHANISM PROPAGATION PATHS

B. Honary, M. Darnell (Hull Univ., England.), and G. Vongas (Defence Research Agency, Cosham, England.) *In* AGARD, Multiple Mechanism Propagation Paths (MMPPs): Their Characterisation and Influence on System Design Jul. 1994 6 p (For primary document see N95-20921 06-32)

In automatic repeat request (ARQ) systems, i.e. those that depend on feedback from the receiver as to the state of the received message, relatively low 'overhead' check digits are required for reliable error detection. A properly designed system of this type can be very reliable, but under poor channel conditions the number of repetitions become excessive. Forward error correction techniques that can correct a mixture of burst and random errors are most suitable for predictable real channels. Recently, an adaptive coding technique has been introduced. The main purpose of an adaptive coding scheme is to permit only the necessary degree of error correction to be applied to the transmitted information according to the channel conditions. The concatenated codes, first introduced by Forney, are formed by cascading two encoders, an inner and outer, where the first is usually a linear binary code, or a combination of two linear binary codes, and the outer is usually a multi-level Reed-Solomon (RS) code over GF(2 exp m). It is known, that with choice of inner and outer codes, concatenated codes become very powerful codes for random and burst error correction. The objective of the proposed paper is to investigate adaptive concatenated codes, which can provide a more efficient error protection in channels with different types of errors. Derived from text

A recently completed study of passive sensing techniques for hf communication systems has shown that these sensing techniques can yield data which may be of use in the control of adaptive hf communication systems. The aim of this paper is to review work carried out to date on these techniques and to examine the feasibility of applying similar techniques to radio systems utilizing higher carrier frequencies, up to around 200MHz, where many propagation modes other than ionospheric skywave may exist. Whilst inputs for the control of adaptive radio systems may be derived from a number of sources, many techniques, such as pilot-tone soundings and the transmission of training sequences, involve radiation of signals which may be undesirable in a tactical situation. System control information may also be derived by monitoring other signals which are already present in related parts of the radio spectrum, allowing more covert operation and avoiding unnecessary pollution of the radio spectrum. Derivation of such control information for use in hf systems has been studied in some detail, utilizing the following types of radio signals existing in the hf band: swept frequency sounder signals radiated by other uses of the hf spectrum, broadcast signals, standard time signals, meteorological data signals (RTTY), and overall statistical occupancy measurements of the spectrum. Some of these techniques would also be applicable to the multimechanism case, provided that the more complex propagation inversion, which is due to the greater range of propagation mechanisms available, can be taken into account. Additional, higher frequency, sources of RF energy which may provide data through passive monitoring, include aeronautical navigation beacons, amateur beacons and various types of radar signals. Use may also be made of low-orbiting satellite signals, although these present tracking problems in terms of doppler shift and give data mainly related to ionospheric scintillation and hence magnetic storm effects. We have analyzed the duty cycle from a very high frequency polar cap path in Greenland. We find that at 35 MHz and 45 MHz the path is often sustained by sporadic E layers rather than by meteor scatter. At the higher frequencies of 65 MHz and 85 MHz we find that the path is generally dominated by meteor scatter modes. The diurnal, seasonal and geomagnetic variations of sporadic E are examined and off line decision aid models are provided to evaluate the magnitude of multiple mechanism propagation on the path. This paper deals with some experimental results. These correspond to radio links operating in the low VHF band (30 - 80 MHz) and in the range 300 - 500 km. For those distances and frequencies, the received signal is affected by fast and slow variations. On the one hand, time-frequency analysis (wavelength transform) shows that the mainly dominant propagation mode is due to partial reflection on random surfaces (sheets). At a given time, only three or four reflections are significant and contribute to the received power. On the other hand, statistics of slow variations are examined and a log-normal distribution is observed. These slow variations are correlated with meteorological data (radiosonde). Best correlations are obtained with atmospheric pressure, refractive index and height of the tropopause. Author

PROBLEMS OF CODING IN MULTIPATH CHANNELS [LES PROBLEMES DE CODAGE DANS LES CANAUX A TRAJETS MULTIPLES]

C. Goutelard *In* AGARD, Multiple Mechanism Propagation Paths (MMPPs): Their Characterisation and Influence on System Design Jul. 1994 9 p In FRENCH (For primary document see N95-20921 06-32)

Transmission channels are essentially multipaths. Multipaths are introduced by birefringences of the medium as in the ionosphere, by inhomogeneity as in the ionosphere and troposphere, or by reflections on obstacles as in urban or tropospheric links. The multipaths create phenomena of interference which introduce modifications of amplitude and phase of the transfer function of the channel. The stationarity of the channels complicates their use, in particular in numerical telecommunications or in teledetection. Countermeasures for fading problems call upon particular techniques of modulation or coding devices. The choice, a priori, of a modulation to carry out a system of telecommunication often involves a complexity of coding necessary to correct the errors introduced by the channel. A general method for the analysis of the channels and choice of the modulation and coding is proposed in this presentation. It is shown that the optimum choice cannot be done without an analysis of the distribution of the errors which depends on the transfer function of the channel, but also on the noise and the interferences. From the knowledge of the transfer function, interferences and noise, it is shown that a general method can be created resulting in a model of error distribution that can support code selection. The codes to be used are often very complex. The technique of interlacing can be used to avoid packages of errors, however quasi interval fadings which appear in the channels with multipaths often make regular interlacing ineffective and it then becomes necessary to consider random or pseudo-random interlacing. The split-step parabolic equation (SSPE) has been used extensively to model tropospheric propagation over the sea, but recent efforts have extended this method to propagation over arbitrary terrain. At the Naval Command, Control and Ocean Surveillance Center (NCCOSC), Research, Development, Test and Evaluation Division, a split-step Terrain Parabolic Equation Model (TPEM) has been developed that takes into account variable terrain and range-dependent refractivity profiles. While TPEM has been previously shown to compare favorably with measured data and other existing terrain models, two alternative methods to model radiowave propagation over terrain, implemented within TPEM, will be presented that give a two to ten-fold decrease in execution time. These two methods are also shown to agree well with measured data. Author

METHODS FOR EVALUATING THE EFFECTS OF CONDUITS AT THE SURFACE OF THE SEA [METHODES D'EVALUATION DE L'EFFET DES CONDUITS A LA SURFACE DE LA MER]

Michel Fournier *In* AGARD, Multiple Mechanism Propagation Paths (MMPPs): Their Characterisation and Influence on System Design Jul. 1994 14 p In FRENCH Sponsored by Direction des Recherches, Etudes et Techniques (For primary document see N95-20921 06-32)

The propagation of radio waves in the atmosphere is determined by the index of refraction which is sensitive to the pressure, temperature and moisture of the air. In the vicinity of the surface of the sea, there is a strong gradient of moisture related to the evaporation of water; it gives rise to a fast decrease of the index of the air creating a conduit of propagation in vicinity of surface. A source located in the interior of the conduit (i.e., at an altitude ranging between that of the minimum of the modified index and sea surface) sees most of its energy remaining captive inside this conduit. This has as an operational consequence - a considerable increase in the range of the radio hardware working in the vicinity of the surface of the sea. In addition, the propagation inside the conduit is characterized by the presence of multipaths related to the successive reflection of the electromagnetic wave on the surface of the sea and the boundary of the conduit. What results is a series of reinforcements and attenuations of the field being propagated in the conduit. Taking into account the practical importance of these effects it is advisable to have suitable methods of evaluation. In this talk three methods are examined: (1) parabolic equation method, (2) method of modes, and (3) method of geometrical optics. The parabolic equation method consists of making an approximation of the wave equation by supposing that the field is propagated around a primary direction. Under these conditions one reduces the equation of propagation to a partial derivative equation of parabolic type which leads to an easy algorithm to work with. The method of modes makes it possible to carry out calculations in an entirely analytical way by supposing that the profile of the index follows a simple law. This method constitutes an analytical reference with respect to the two other methods which are numerical. The method of geometric optics is an asymptotic method. It consists of considering the trajectory of the rays resulting from the source by solving the eikonal equation. The intensity of the electromagnetic field can be given in conjunction with the equation of the trajectories; the calculation of the divergence of the wave vector tangent to the ray passing by the point where the field is evaluated. One thus obtains a system of ordinary differential equations which can be solved numerically by the method of Runge-Kutta. Each one of these methods is analyzed and a comparison between them is carried out on a number of concrete examples. In each case the theoretical limits, the advantages, and the limits of use of the three methods are highlighted. Transl. by CASI

Telecommunication between a fixed basic station and a vehicle moving on the surface of the ground are subjected to multiple reflections. When the frequency of the carrier is of the order or higher than 1 GHz, the majority of the obstacles located between the emitter and the receiver has dimensions much larger than the wavelength and a predictive model of the conditions of propagation can be based on the theory of rays and in particular on the uniform theory of diffraction (UTD). The first part of this article presents a brief review of the mathematical formalism and the way of introducing the complex permittivity of the ground into the ideal models. In the case of propagation in an urban environment, a comparison between the results obtained using the UTD and those based on approximate models which account for multiple diffractions is carried out. An important geometrical configuration for which the multiple reflections play a very important part relates to the propagations in tunnels. The analysis is undertaken by successively considering the intrinsic propagation in the tunnel, i.e. by supposing that the tunnel is infinitely long, then the free-tunnel transition space. The study is carried out in the frequency domain then temporal domain closely connected to highlight the fluctuations of amplitude of the signal and the delays to the multipaths. The theoretical predictions are then compared with the experimental results. Transl. by CASI

Multipath, jamming, listening and detection are the main limitations for mobile radio communications. Spread spectrum techniques, especially frequency hopping, can be used to avoid these problems. Therefore, a wideband simulation for multipath mobile channels appeared the most appropriate evaluation technique. It also gives useful indications for system characteristic improvements. This paper presents the design and realization of a new UHF-VHF propagation simulator, which can be considered as an extended version of Bussgang's one. This frequency hopping simulator (up to 100,000 hops per second) is wideband thus capable to deal with spread spectrum signals. As it generates up to 16 paths, it can be used in almost all mobile radio propagation situations. Moreover, it is also able to simulate high mobile relative speeds up to 2000km/h such as air-air communication systems. This simulator can reproduce, in laboratory, 16 rays Rician or Rayleigh fading channels with a maximum time delay of about 15 ms. At the highest frequency of 1200 MHz, Doppler rates up to 2 kHz can be generated corresponding to vehicle speeds up to 2000 km/h. Let note that the Bussgang simulator was defined for narrowband and fixed radio communications. In both equipments, in-phase and quadrature signals are obtained using two numerical transversal filters. Simulation results were derived in various situations especially in terrestrial urban and suburban environments, where they could be compared with measurements. The main advantage of the simulator lies in its capacity to simulate the high speed and wideband mobile radio communication channels. Author

Radiowave propagation on mixed land/sea paths is affected by both atmospheric refraction and terrain effects. The parabolic equation method provides a numerical solution for calculation of field-strength in these circumstances. We give a few applications of the finite-difference PE method, which is particularly well-adapted to problems where ground effects are important. A case in point is that of detection of low targets above a rough sea surface. For air-defense applications, PE computing requirements are prohibitive. We describe a novel method, the horizontal PE method, which allows fast computation of signal strength in large domains, and apply it to calculations of radar coverage. Author

Satellite-to-ground propagation paths are frequently affected by tropospheric refraction and ducting at very low elevation angles. Common effects are substantial enhancements of signals at ranges that would normally be beyond the horizon, and severe distortions of the patterns created by the coherent interferences of multiple propagation paths, in particular the direct and sea-reflected signals. Traditional methods to model tropospheric ducting effects, such as waveguide or parabolic equation methods, are difficult to apply to typical satellite heights. This paper will describe a parabolic-equation and ray-optics hybrid method to model these sometimes important effects, and compare modelled and measured results using a 1000-km high satellite transmitting at 1239 and 2891 MHz. THE LORENTZ RECIPROCITY THEOREM AS A CONSISTENCY TEST FOR PROPAGATION MODELS

Richard A. Paulus *In* AGARD, Multiple Mechanism Propagation Paths (MMPPs): Their Characterisation and Influence on System Design Jul. 1994 8 p (For primary document see N95-20921 06-32)

Copyright Avail: CASI HC A02/MF A04

Modeling of electromagnetic propagation in the troposphere has been advanced in the last decade to the point where both the vertical and horizontal variation of refractivity can be accommodated readily. In particular, parabolic equation models inherently allow for lateral and vertical inhomogeneities. A hybrid ray-optics/parabolic equation model is utilized to predict propagation loss for a range-varying refractive structure to demonstrate the model obeys the Sommerfeld-Pfrang statement of the Lorentz Reciprocity Theorem. For a radar system in a maritime environment, the probability of detection of a target at a low altitude is strongly dependent on the conditions of the atmosphere and the sea surface. In order to determine the detection probability of a target at low altitude, these conditions should be taken into account. This paper presents numerical methods to calculate electromagnetic propagation in an evaporation duct and to calculate sea clutter returns. Author

By inducing scintillation of the transmitted signals, atmospheric turbulence affect both satellite and line-of-sight communication systems in the millimeter-waves range. After a characterization of the scintillation effect from theory and experiments, this paper presents two deterministic models developed at the Microwaves Laboratory U.C.L. for the simulation of scintillation. The first model accounts for the physical process of cloud induced turbulence that yields scintillation on satellite links and the second one deals with the turbulence in the lower atmospheric layer that affects terrestrial paths. These models allow to retrieve the turbulent configuration that produce scintillation, to simulate the scintillation effects on various links and finally to predict the impact of scintillation on the performances of communication systems. PROPAGATION MEASUREMENTS ON A TROPOSCATTER LINK IN THE CANADIAN HIGH ARCTIC

C. Bilodeau and K. S. McCormick *In* AGARD, Multiple Mechanism Propagation Paths (MMPPs): Their Characterisation and Influence on System

Design Jul. 1994 7 p Sponsored by Dept. of National Defence (For primary document see N95-20921 06-32)
Copyright Avail: CASI HC A02/MF A04

Experimental results of radio propagation measurements at 853 MHz are given for a 500 km troposcatter link in the Canadian High Arctic. The experimental data were acquired using a narrow band measurement system that was developed to permit a transmitting power of only 100 Watts while using a 4.5 meter dish at each end of the link. The system includes a digital signal processor (DSP) receiver for signal strength computation and a high stability noise source reference for amplitude calibration. The main characteristics of this system are described in this paper. Detailed fading distributions are presented for examples of slow and fast fading periods and compared with Rayleigh distributions. An estimate of the long term median path loss is made and compared with values predicted using accepted techniques. The results are believed to be the first ever presented for a microwave troposcatter link above the 80th parallel. Author

A bistatic radar test bed has recently been developed to measure the depolarization behavior of clutter at large bistatic angles in Eastern Massachusetts. Results presented in this paper describe the co- and cross-polarized S-Band NRCS for low resolution (300m by 300m) forested clutter cells viewed at low grazing angles. We also describe the variation in mean scattered power versus linear receiver antenna orientation angle for both vertical and horizontal transmitted polarizations. Measurements of a 20 km by 20 km region of rolling hills show that vertical copolarized NRCS exceeds horizontal copolarized NRCS by an average of 8 dB over a range of bistatic angles from 100 degrees to 160 degrees. The average polarization ratio is minus 12 dB for vertical transmitter polarization and minus 5 dB for horizontal transmitter polarization. For both transmitter polarizations and variable linear receiver antenna polarization, maximum scatter power was observed when transmitter and receiver antennas were copolarized while minimum received power was observed when the antennas were crosspolarized. Power fluctuation statistical distributions are approximately exponential for all linear receiver antenna polarization angles. Author

TIME BEHAVIOR AND FREQUENCY RESPONSE OF THE MICROWAVE PROPAGATION CHANNEL DURING MULTIPATH PROPAGATION

D. Rana, M. Sylvain, and A. R. Webster (University of Western Ontario, London, Ontario.) *In* AGARD, Multiple Mechanism Propagation Paths (MMPPs): Their Characterisation and Influence on System Design Jul. 1994 12 p Sponsored in part by the Communications Research Centre and the Natural Sciences and Engineering Research Council of Canada (For primary document see N95-20921 06-32)
Copyright Avail: CASI HC A03/MF A04

In this paper, ray-tracing simulation is used to model the dynamic behavior of the propagation channel in presence of a single super-refractive layer. Three typical mechanisms of layer formation and evolution are simulated according to experimental observations. (1) A ground-based layer formed by nocturnal cooling of the Earth's surface, its intensity increasing with time, (2) an elevating layer, that is a ground-based layer which weakens in rising, its intensity decreasing linearly with height, and (3) an elevated layer formed when a warm dry air mass is produced in the upper atmosphere; this layer grows with time. For each of these three types of layer, a ray-tracing program is used to compute the variations with time of the ray parameters and of the received signal level. As the statistics of the speed of layer formation and evolution are not precisely known, the time scale used in this study is somewhat arbitrary. However, this technique allows one to identify three typical fading patterns and to help interpret the physical mechanisms involved in the generation of multipath propagation. The frequency selective nature of the propagation channel bandwidth is then investigated over a 10.7-11.7 GHz in looking for the influence of each type of layer on the transfer function. Some experimental evidence relating to, and confirming, the predicted behavior values is also considered. Author

This paper describes the features of measurement equipment developed to measure impulse response estimates of mobile radio channels in less than a ms per measurement. The development of such equipment was required to measure mobile radio channels in realistic operating scenarios, in a normal sized vehicle moving at typical speeds in different environments. Up to speeds of 70 km/hr, the measurement period is short enough to assume the equipment is measuring the same channel during the whole sampling interval. AT the transmitter end of the measurement system, a wideband signal (10 MHz) is produced by modulating a carrier frequency with a 511 bit pseudo random sequence at 5 Mb/s and transmitted through the radio channel. The received signal is down-converted to 70 MHz and demodulated by a complex demodulator. The quadrature baseband signals at the demodulator outputs are then filtered and sampled at high speed by two fast digitizers. During this process, the data are stored in large memory banks to allow a fast sampling rate during a long period of time. Data are transferred to laser disks for further processing in the laboratory. Impulse response of radio channels are estimated by performing a software correlation between a measurement system back to back reference and real time measurements. A minivan was modified to hold the receiver, digitizers, memory banks and the computer. A shaft encoder was attached to its rear left wheel to trigger measurements while moving. Features of the system are discussed along with the effects of data block length, signal to noise ratio, sampling rate, memory size and phase stability on the design of the measurement equipment. Finally, some measurement results are presented and discussed. Author

LINE-OF-SIGHT MULTIPATH PROPAGATION MEASUREMENTS AT 15 GHz OVER 500 MHz BANDWIDTH

M. Touati, G. ElZein, and J. Citerne *In* AGARD, Multiple Mechanism Propagation Paths (MMPPs): Their Characterisation and Influence on System Design Jul. 1994 10 p (For primary document see N95-20921 06-32)
Copyright Avail: CASI HC A02/MF A04

An experimental wideband grazing radio link at 15 GHz has been set up on a 17.6 Km line-of-sight between Laille and Rennes to measure the variations of the propagation medium characteristics (attenuation and group delay versus frequency) due to meteorological effects. For this, a meteorological system was set up at the receiver station in order to measure the variations of the meteorological parameters (temperatures, pressure, rain precipitation, speed and direction of the wind). Consequently, the atmosphere refractive index is obtained. A particular interest is given to the occurrence of multipath fading in clear air caused by low-level layering in the troposphere. The collecting and recording of the propagation data (attenuation and group delay), from the MLA (microwave Link Analyzer), and that which relates to the meteorological characteristics, from the meteorological station, are executed using a computer program in a sequential manner. The channel impulse response, corresponding to each measured data, is calculated to deduce the number of rays detected and their different delays respectively. Besides this and using the meteorological parameters data acquired, the refractivity gradient is calculated in order to correlate the multipath fading occurrence to the meteorological parameters. The use of satellite seems to be an answer to the radioelectrical covering problem for the mobile communications, particularly in the low populated areas. Frequency bands at 1.5 and 2.5 GHz have been dedicated to these future services. Satellite-mobile links will be much more affected by propagation phenomena than the existing links between satellites and fixed stations. The reasons for that are twofold: The probable use of LEO (Low-Earth-Orbit) satellites instead of GEO; such satellites will have to be received at relatively low elevation to limit their number; the use of mobile communication terminals with small and non directive antennas that must work in various environments instead of terrestrian stations located at carefully chosen places and equipped with large diameter paraboloids. These propagation phenomena mainly consist in the fading of the signal level (shadowing of the link), and a frequency selective fading due to multipath propagation. The experience run by C.R.P.E. is aimed at a better understanding of the satellite-mobile propagation channel at fixed frequency as well as on a large band. In this paper, we discuss preliminary results from a series of propagation measurements performed (by lack of any experimental satellite) on an experimental radio link at 1.45 GHz on a of 20 MHz bandwidth between a helicopter flying at a height of 2 km and a mobile receiver. The whole experiment has been run in a rural environment in Brittany (France). In a first part, we illustrate the quality of the data collected during the experiment on a typical case study and give a possible physical interpretation of the observed phenomena. Then we present statistical results concerning the various characteristics (attenuation and delay spreads) of the propagation channel. Finally, we discuss the problem of using a helicopter (flying at a height of 2 km) as a substitute for a satellite at about 1000 km and try to estimate to what extent it is possible to use the data collected during this experiment to characterize the satellite-mobile channel. To do that, both the helicopter-mobile and the satellite-mobile propagation channels are simulated under the same environmental conditions. Author

At intervals over a period of several years, we conducted simultaneous troposcatter measurements at frequencies of 4.95 and 15.73 GHz on a 161 km path in the northeastern United States. This ensured a fair comparison within a largely unspecified but identical propagation medium. Besides signal level, both systems yielded Doppler information on the propagation mechanism. In addition, the Ku-band system provided delay resolution by pseudorandom phase modulation. On the basis of these data, three primary propagation mechanisms could be identified: clear air turbulent scatter, rain scatter, and ducting. Criteria are given for the identification of these mechanisms along with the resulting received signal level and delay spread distributions under each propagation condition. Author

PTT Research and Delft University of Technology examined the merits of angle diversity for multipath fading reduction on digital microwave links. A dual-polarized hybrid reflector array, suitable for beam switching in the vertical plane, was designed and produced. The antenna specifications were based on extensive propagation studies. The antenna was tested for two years on a 45 km hop in The Netherlands. It was found that switching between the antenna beams is superior to adaptive (maximum power) combining. Switching reduces the time that the Bit Error Ratio (BER) exceeds 10(exp -3) by a factor 27. Author

The goal of this work is to investigate the design issues implied by multipath effects for a high bandwidth communication network consisting of platforms in a Navy battle group. This communication network is designed to operate using super-high frequency (SHF) or ultra-high frequency (UHF) line-of-sight (LOS) propagation, and must be robust to variations in link quality due to platform motion or deletion, as well as to the effects of multipath propagation. High bandwidth in this context implies data rate in excess of 1.544 megabits per second (Mbps), known as 'TI' in the commercial world. Multipath nulls at the above frequencies can render links useless at certain ranges. In this work, we briefly discuss the well-known methods of height and frequency diversity, as well as a less frequently used but potentially powerful method of 'path diversity' through networking, to alleviate the ill effects of multipath nulls. The communication system configurations discussed are appropriate for expected platform separations in post-Cold War battle group scenarios, which envision most platforms within line-of-sight (LOS) distance from each other, i.e., separated by no more than about 20 nautical miles (nmi). MULTIPATH IMPACT ON GROUND-BASED GLOBAL POSITIONING SYSTEM RANGE MEASUREMENTS: ASPECTS OF MEASUREMENT, MODELING, AND MITIGATION

G. J. Bishop and E. A. Holland (Northwest Research Associates, Inc., Bellevue, WA.) *In* AGARD, Multiple Mechanism Propagation Paths (MMPPs): Their Characterisation and Influence on System Design Jul. 1994 10 p (For primary document see N95-20921 06-32)

Multiple mechanisms propagation paths (multipath) can be the most important error source in ground-based Global Positioning System (GPS) measurement of range to the satellites. This multipath error, arising from a combination of the direct path and reflections from objects relatively close to the receiving antenna, can at times exceed the ionospheric delay error, which the two-frequency (1228 and 1575 MHz) GPS signal format is designed to measure and correct. GPS multipath can seriously degrade Differential GPS (DGPS) navigation, geodetic measurements, ionospheric monitoring, and other GPS applications, yet the source of the problem may not be evident without the use of specialized tests. Several techniques have been proposed to reduce the effects of GPS multipath; these include: improved receiver technology, specialized antenna designs, and various modeling or filtering approaches. This paper illustrates the nature of the two-frequency GPS multipath problem with measurement data from typical ground-based installations, exhibiting variation in multipath conditions, ranging from low to quite high for the varying geometries of the available satellite tracks. Leading mitigation techniques are reviewed, with emphasis on multipath modeling. A new simple modeling approach currently being studied by Phillips Laboratory is discussed. This technique takes advantage of the daily repetition of the GPS observation geometry from a ground station to create a 'multipath template' specific to each satellite pass, and reduce multipath effects on successive days. Data is presented showing significant improvement in a severe multipath environment and contrasting the effectiveness of this approach with all-sky modeling techniques. Mitigation techniques for GPS multipath show potential to enable GPS ground-based range and ionospheric measurement to greatly reduce errors at low elevation angles, leading to improved accuracy and wider coverage area capability. Propagation mechanisms have a detrimental effect on the accuracy of satellite positioning systems such as GPS and GLONASS. The ionosphere at times of high activity will cause the greatest error due to the propagation medium. This paper describes a dual GPS/GLONASS receiver that is capable of measuring the ionospheric delay in the measured GLONASS pseudo ranges using both the code and carrier phases. This allows the pseudo ranges to be corrected for ionospheric delay and a more accurate position solution to be calculated. This paper describes the receiver architecture and fundamental accuracy; receiver measurement noise and calibration are also discussed before the impact of propagation mechanisms on the measurements are investigated. The measurement of the line of sight ionospheric delay, from a GLONASS satellite, is shown and compared with the GPS transmitted ionospheric model. An example of GLONASS P code navigation is given with and without correction for the ionosphere. Author

In recent military operations trans-ionospheric satellite to ground communications have been utilized in the equatorial region. One problem for the predominantly 250 MHz systems has been fading due to irregularities in the region within plus and minus 20 degrees of the magnetic equator. A similar problem has been encountered at high latitudes. For minimizing the effect of the fading, one might expect that radio links sufficiently separated in frequency and polarization would be effective in combating scintillation. Unfortunately frequency separations would have to be of the order of 100 MHz to obtain an adequate diversity improvement. The use of right and left circular polarization or of orthogonal linear polarizations is not effective. However, time diversity is a demonstrated procedure for overcoming scintillation but there is a loss of using coding or redundancy and a reluctance to complicate the system with modems. If the paths from a single satellite are sufficiently well separated then fading on two links is uncorrelated and diversity gain may be achieved. Unfortunately at equatorial latitudes separations of the order of a kilometer are involved. Another use of 'space diversity' can be effective. If the paths from two satellites with spacing between them are available and there is recognition that scintillation is causing the fading on the path to one satellite, then operators can utilize the path to a second satellite. For equatorial paths the operator must be alert as to the time development of irregularities and the dynamics of plume development. The differences in activity on the paths are due to two aspects of the irregularity plume i.e. the start time as the sunset moves westward and the spacing between plumes on the very active days. Examples of the time difference between the start of equatorial scintillations on one path versus that of another have been recorded in many sectors of the world. The results of these studies as applied to the problem of multiple paths will be shown. At high latitudes during moderate magnetic activity, it is possible to find paths that are not dominated by irregularities. However at auroral latitudes when a magnetic storm commences, the irregularity development moves equatorward with great rapidity and encompasses large areas. It is then difficult to find a path free of irregularities. Author

The general theory describing reflection of electro-magnetic waves from irregular reflectors was formulated by using path integral techniques. The general formulae reproduce the well known reflection coefficients for wave scattering from random rough surfaces derived by using Kirchhoff's theory or perturbation theory. The theory was used to determine the degradation of an OTH radar signal scattered from irregular Artificial Ionospheric Mirrors (AIM). The cases of density irregularities induced by fluctuations in the ambient neutral density and by fluctuations in the heater power were separately examined. Scaling laws and bounds for minimal signal loss were derived. Author

Analysis of approximately one year's data from an operational OTH radar shows that equatorial clutter, originating in the ionosphere in regions up to 14,000 km from the radar, directly impacts the radar's performance. The radio wave propagation to these regions often involves from three or more ground hops depending on the radar's azimuth. These phenomena are important to all OTH radar systems in that great circle paths always cross the magnetic equator. The special data processing developed for this program uses both the long range (to 8000 nm) wideband 6 to 28 MHz) backscatter ionograms made routinely at selected azimuths and the radar's amplitude, range and Doppler data format, measuring the frequency of occurence, location and intensity of the clutter as a function of time and azimuth. These data indicate that intense ionospheric irregularities connected with the nighttime equatorial activity produce sufficient Doppler spread scattered energy that directly affects the performance of the radar. With the Parametric Ionospheric Model developed at the Phillips Laboratory and numerical ray tracing the specific interaction regions for the radar signal and the ionospheric irregularities are shown and an explanation for the observed temporal behavior is proposed. Several mechanisms for Doppler spreading of the clutter signal are also reviewed. Author

The electromagnetic wave propagation in the ionosphere is complex; the anisotropy and the inhomogeneity introducing multiple paths and the non stability of the Doppler effects. The ionospheric models usually used make it possible to account for the multiple paths and the Doppler shifts. According to these models, based on ray tracings, it appears that there is only one triplet (amplitude, Doppler, time travel) which makes it possible to plot simple diagrams. The experimental observation shows that, if one finds the signatures envisaged in the classical theory of the ray tracings for the signals of great amplitude, one observes, with systems of measurement of great sensitivity, signals of low amplitude which seem to translate the existence of diffuse propagations. The results of an oblique bistatic survey and of a backscattering study given in this presentation, show the appearance of effects of the second order. A method of characterization of these effects is proposed by the introduction of measurement of fractal dimensions of the functions of scattering, obtained by a method of high resolution spectral analysis. The performance of communications equipment (especially data modems) designed to work over high frequency paths which can propagate by a number of different mechanisms is dependent on their ability to work with a wide range of signal to noise conditions and with varying degrees of frequency and time dispersion. The latter phenomena are a particular problem for systems operating over high latitude paths and yet there appears to be little available data documenting their severity or frequency of occurrence. DAMSON (Doppler And Multipath SOunding Network) is an oblique channel sounding system which has been developed by the UK Defence Research Agency (DRA) to measure a number of real-time channel parameters using low power pulse compression waveform transmissions. Extensive use is made of digital signal processing techniques. The system will allow signal time-of-flight, time dispersion (multipath dispersion), frequency dispersion (Doppler spread and Doppler shift) and signal strength to be measured over point-point communications paths. The DAMSON experiment is to be deployed to make measurements over a number of mid and high-latitude paths. This paper provides an introduction to the DAMSON system, its basic operation and measurement performance. The initial experiments to be conducted and the associated system deployment are presented. We present a system which is able to separate the propagation paths and also to identify the type of polarization of the modes. The studied links are between Monterfil (48 deg 05 N latitude, 2 deg W longitude) and all types of known location transmitters which work on carrier. The experimental analysis is performed using a 'goniopolarimeter' which is a device determining both the arrival angles (goniometrical function) and the type of polarization of the corresponding incoming skywaves. We apply a high resolution non linear frequency analysis associated with a reiterated method of filtering matched to this polarization. Author (revised)

The paper introduces the principles of a new macroscopic diversity scheme employing maximum likelihood, symbol-level, diversity combining. The performance of the scheme is compared with that of other classical post-detector diversity combining methods. It is shown that the new scheme has a performance similar to the classical techniques; however, its complexity is significantly lower. The application of macroscopic diversity in the HF band is then described, and the results of practical on-air trials presented. Author

In this work three superresolution direction finding algorithms for use with arbitrary array geometries are described, all of which are capable of dealing with coherent signals, as typically found in the multi-path environment. DOSE is a quick single snapshot algorithm developed by the authors which operates on the received data vector. The IMP and Maximum Likelihood (ML) algorithms are used to process time averaged data covariance matrices. All three algorithms attempt in different ways to find a multi-dimensional solution to the inverse problem of direction finding. It is shown that calibration of arrays of identical elements is simplified by the use of these multi-dimensional algorithms when compared to 1 dimensional methods such as MUSIC. A common methodology for the implementation of these multi-dimensional algorithms is presented, and a quick method of implementing the ML algorithm and determining the number of signals present is described. In this paper, we present the use of high resolution techniques and polarization diversity in order to analyze HF links in ionospheric propagation, links which are characterized in general by the presence of several modes of propagation giving rise to several incident waves with the reception. These modes are strongly correlated and can have very different polarizations. The high resolution techniques have the capacity to simultaneously measure several incident waves present in a given frequency channel of analysis, and are thus adapted particularly to the situation of jamming where a frequency and/or temporal separation is no longer possible. The use of a network with polarization diversity allows, beyond obtaining certain parameters of polarization, an increase in the resolution of the methods considered, because of the difference in polarization of the modes. A better knowledge of the phenomenon of propagation waves in this medium is the anticipated result of the application of these techniques. For a given connection and at first approximation (one neglects the effects due to the 'tilt', or the rebound on a tilted ground), the modes arrive under the same azimuth with different angles of elevation. In the experiment described in this paper, the measurement of the angles of elevation is made by supposing a knowledge of azimuth. Thus we use a linear network and let us direct it in order to obtain good performances for the estimate of the angles of elevation. The method high resolution with diversity of polarization used is method MUSIC adapted in order to take account of the use of sensors having gains different according to polarization from the received wave. MEASUREMENTS OF RADAR BACKSCATTER FROM THE OCEAN SURFACE AT 94 GHz AS A FUNCTION OF WIND SPEED, DIRECTION AND THE MODULATION BY THE OCEAN WAVES DURING THE SAXON-FPN EXPERIMENT

Hans-Hellmuth Fuchs *In* AGARD, Multiple Mechanism Propagation Paths (MMPPs): Their Characterisation and Influence on System Design Jul. 1994 7 p (For primary document see N95-20921 06-32)

Copyright Avail: CASI HC A02/MF A04

As part of the joint German/US SAXON-FPN remote sensing experiment a series of mm-wave radar backscatter measurements were carried out in the German Bight of the North Sea in November 1990, 1991 and August 1992. The dependence of the reflectivity sigma(sup o) on wind speed and direction was determined by means of a 94 GHz (W-band) radar mounted on the German Research Platform North Sea (FPN). The radar backscattering measurements were performed at an incidence angle of 45 deg and at azimuth angles relative to the wind direction ranging from upwind to crosswind. Based on the data evaluation of the three measurement periods values for the wind speed exponent gamma defined by an empirical relation between the reflectivity sigma(sup o) at vertical polarization and the windspeed U measured at a height of 46 m above mean sea level at the FPN were obtained. The values of gamma range between 2.33 and 2.50 depending on wind direction and the wave spectrum. This result shows that the wind speed exponent at W-band is higher than those at X-, Ku- and Ka-band indicating that either an enhanced generation of higher amplitudes of short waves in the millimeter range or other processes exist like specular scattering from facets reinforcing the backscatter cross section. SOUNDER CALIBRATION WITH BACKSCATTERING FROM LOSQUET ISLAND IN THE PRESENCE OF MULTIPATHS [CALIBRATION DU SONDEUR A RETRODIFFUSION DE L'ILE LOSQUET EN PRESENCE DE MULTI-TRAJETS]

F. Gauthier, J. Y. LeSaout, and R. Fleury *In* AGARD, Multiple Mechanism Propagation Paths (MMPPs): Their Characterisation and Influence on System Design Jul. 1994 12 p In FRENCH (For primary document see N95-20921 06-32)

Copyright Avail: CASI HC A03/MF A04

The precise localization of the areas of the ionosphere by HF forward-scatter radars depends on the parameters characteristic of the propagation at the time of the survey, and often requires the use of calibration techniques. To gauge the data of the sounder with backscattering data from the Losquet Island, the National Center of Studies of Telecommunications (CNET) implemented a HF mobile monofrequency responder radar. This paper presents the results of surveys obtained in 'scanning of site' mode with this responder and established to approximately 1000 km the Losquet Island; these data are used to calculate the position of the responder. It is shown that the multipaths are the primary source of the statistical error of localization in radial distance and that the use of simple methods of treatment allows the reduction of this error. ROUTING OF UNIDIRECTIONAL PACKET RADIO FOR WIDE-AREA PAGING NETWORK CONTROL AND MAINTENANCE

J. Honkanen 1994 67 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(PB95-104428; ISBN-951-22-2062-8) Avail: Issuing Activity (National Technical Information Service (NTIS))

The object of this report is to present ways to design a packet radio system for the paging network control and maintenance. The main interest is laid on the routing of the packet radio, but also other design questions of the packet radio and the paging network systems are considered too. In order to obtain an efficient packet radio network that is also robust against radio path fluctuations and interferences, a new quality controlled packet radio model is presented. Two different routing and scheduling methods that are based on the quality controlled packet radio model are proposed. The first method consists of several heuristic and non-iterative algorithms. The second method is iterative, and it is an implementation of the evolutionary algorithms. NTIS

STUDY ON THE REACTION KINETICS IN PULSED RF DISCHARGES UNDER RIE CONDITIONS Ph.D. Thesis

Jacobus Antonius Gij Baggerman (Philips Research Labs., Eindhoven, Netherlands.) 26 Oct. 1993 133 p

(PB95-107868; ISBN-90-74445-07-1) Copyright Avail: Issuing Activity (National Technical Information Service (NTIS))

In the present-day electronics industry, reactive ion etching (RIE) is a technique widely used to etch thin films anisotropically. The subject of this thesis is the determination of (reaction) kinetics of rf discharges under RIE conditions. Special attention is given to determining quantitatively the rise and decay of densities and energy distributions of plasma particles. A production-type RIE reactor was used for all experiments. In chapter 2 the ion density is determined by LIF spectroscopy in a model (N2) discharge under RIE conditions. Chapter 3 concerns energy-flux density measurements on the various parts of the etch reactor in contact with a 30 Pa nitrogen rf discharge. Chapter 4 concerns the etch mechanism of various organic polymers in oxygen and argon of discharges under RIE conditions studied by performing energy-flux density and ion-flux density measurements on the powered electrode. The polymers of interest are a novolac-based photoresist, polyimide and polymethylmethacrylate (PMMA). The density and the reaction kinetics of ground-state methylidyne (CH radical) are determined by LIF in order to determine whether small molecules in addition to atoms are sputtered from the polymer surface. In chapter 5 a model is set up in which diffusion of CH from the substrate into the gas phase and chemical reactions in the gas phase are taken into account. NTIS

ADAPTIVE DETECTION IN STATIONARY AND NONSTATIONARY NOISE ENVIRONMENTS

Paul Monticciolo 24 Feb. 1994 69 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(Contract F19628-90-C-0002)

(AD-A279581; TR-937; ESC-TR-93-238) Avail: CASI HC A04

This report describes the statistical performance of several radar-based adaptive detection schemes in both stationary and nonstationary noise and interference environments. The detectors under study must be able to correctly determine the presence of a target in a range gate with a high degree of probability given that the probability of misclassification is a fixed small value. The hostile noise environment is assumed to consist of possibly time-varying, spatially correlated interference along with Gaussian background noise. In a typical radar environment, the mean value of the returned radar signal and the noise covariance matrix are unknown parameters; therefore, generalized likelihood ratio test procedures were used to develop decision rules that meet the Neyman-Pearson criterion. Three major cases of interest were examined. First, the single-pulse test developed by Kelly is reviewed. The multiple-pulse return test case is extremely complicated and was divided into distinct detector forms: noncoherent and coherent. The performance of each detector is a function of the signal-to-noise ratio, the number of radar pulse returns used in the decision rule, and the quality of the covariance estimate. DTIC

LOW-FREQUENCY IMAGE THEORY FOR A CURRENT DIPOLE IN FRONT OF A PERMEABLE SPHERE

Johan C.-E. Sten May 1994 17 p See also PB93-179075 Sponsored by Academy of Finland

(ISSN 0784-848X)

(PB95-127676; ISBN-951-22-2131-4) Avail: CASI HC A03/MF A01

Image theory, previously developed for a low-frequency current source in front of a dielectric sphere, is formulated for the magnetically permeable sphere. The low-frequency image source corresponding to an electric dipole outside the sphere arises only when the orientation of the dipole is tangential to the surface of the sphere. Two alternative image representations are developed. One is a combination of a magnetic strip current and a bifilar magnetic line current, both flowing between the center of the sphere and the Kelvin inversion point on the axis connecting the sphere and the dipole. The other is a combination of a magnetic strip current and an electric strip current flowing orthogonally to each other. NTIS

EIGENMODE METHOD FOR ELECTROMAGNETIC SYNTHESIS OF DIFFRACTIVE ELEMENTS WITH THREE-DIMENSIONAL PROFILES
Eero Noponen and Jari Turunen 1994 13 p
(ISSN 0355-7790)
(PB95-127726; TKK-F-A726; ISBN-951-22-2038-5) Avail: CASI HC A03/MF A01

The authors extend the rigorous eigenmode theory of binary surface-relief gratings to accommodate three-dimensional-modulation profiles, to formulate a synthesis problem for doubly-periodic resonance-domain diffractive elements, and to demonstrate some of its symmetry properties. Several solutions for multiple beam splitters with about 90% transmission-mode diffraction efficiency are obtained by nonlinear parametric optimization. The polarization sensitivity and the required fabrication accuracy are analyzed for some solutions. NTIS

CELL LOSS ANALYSIS OF TWO-CLASS PRIORITY GENERALIZED KNOCKOUT SWITCH
Jian Ma and Kauko Rahko 1994 11 p
(ISSN 1235-8975)
(PB95-127742; ISBN-951-22-1932-8) Avail: CASI HC A03/MF A01

Since services require different quality of service, an asynchronous transfer mode (ATM) switch must be capable of handling the requirements of different services. In this letter, we introduce a two-class priority scheme to Knockout Switch (KS) and Generalized Knockout Switch (GKS). The priority switches achieve much lower loss rate of high-priority cells than no-priority switches. Using the priority scheme in the GKS is more efficient than in the KS to reduce the interconnect complexity of switch. NTIS

SMALL ANTENNAS FOR COMMUNICATION OVER SEA ICE Patent Application
Paul Mileski, inventor (to Navy) 4 Oct. 1993 13 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-D016206; US-Patent-Appl-SN-130940) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The invention described herein relates to an antenna system which makes use of the waveguide properties of sea ice. The antenna system broadly includes at least one antenna wire extending along and preferably in contact with a sea ice surface for transmitting and receiving substantially vertically polarized radio waves. In a first embodiment, the antenna system has a single antenna wire connected to a tuner at one end and grounded to seawater at a second end. The antenna system also has a second length of wire attached to the tuner. The second wire passes through a hole in the sea ice and is also grounded to the seawater beneath the sea ice. In an alternative embodiment, only the second wire is grounded to the seawater beneath the sea ice. The single antenna wire in this embodiment is ungrounded. In yet another embodiment, the antenna system comprises a dipole antenna wire laying on the surface of the sea ice and being connected to a radio for transmitting and receiving radio signals. DTIC

THREE-DIMENSIONAL GROUND PENETRATING RADAR IMAGING USING MULTI-FREQUENCY DIFFRACTION TOMOGRAPHY
J. E. Mast and E. M. Johansson Jul. 1994 9 p Presented at the Annual Meeting of the Society of Photo-Optical Instrumentation Engineers, San Diego, CA, 24-29 Jul. 1994
(Contract W-7405-eng-48)
(DE94-016687; UCRL-JC-116340; CONF-940723-13) Avail: CASI HC A02/MF A01

In this paper we present results from a three-dimensional image reconstruction algorithm for impulse radar operating in monostatic pulse-echo mode. The application of interest to us is the nondestructive evaluation of civil structures such as bridge decks. We use a multi-frequency diffraction tomography imaging technique in which coherent backward propagations of the received reflected wavefield form a spatial image of the scattering interfaces within the region of interest. This imaging technique provides high-resolution range and azimuthal visualization of the subsurface region. We incorporate the ability to image in planarly layered conductive media and apply the algorithm to experimental data from an offset radar system in which the radar antenna is not directly coupled to the surface of the region. We present a rendering in three-dimensions of the resulting image data which provides high-detail visualization. DOE

RESONANT PHOTON-GRAVITON CONVERSION IN EM FIELDS: FROM EARTH TO HEAVEN
Pisin Chen Sep. 1994 9 p Presented at the 1st International Conference on Phenomenology of Unification From Present To Future, Rome, Italy, 23-26 Mar. 1994
(Contract DE-AC03-76SF-00515)
(DE95-002784; SU-SLAC-PUB-6666; CONF-9403118-2) Avail: CASI HC A02/MF A01

Gravitational radiation from high energy particles in modern accelerators is reviewed. We point out that the most effective way for laboratory production and detection of gravitons is through resonant photon-graviton conversion in a strong external EM field. Specific example using crystal channels for the (gamma) (yields) g (yields) (gamma) process is given, where the physical parameters needed for such a test appears to be reasonable. As another application of this effect in astrophysics, we show that the coupling between the cosmic microwave background radiation (CMBR) and the primordial magnetic field can induce a frequency-independent fluctuation in the photon flux. Using the observed CMBR fluctuation, we derive a bound on the primordial field strength. The effect can also convert the relic gravitons into photons. For the string cosmology it gives a new bound on the Hubble parameter at the Big Bang. DOE

AN OBJECT-ORIENTED IMPLEMENTATION OF THE Xpress TRANSFOR PROTOCOL
W. Timothy Strayer, Simon Gray, and Raymond E. Cline, Jr. 1994 14 p Presented at the 2nd IWACA Workshop, Heidlegerg, Germany, 26-28 Sep. 1994 Sponsored by AT and T Bell Labs.
(Contract DE-AC04-76DP-00789)
(DE95-001506; SAND-94-8718C; CONF-9409236-1) Avail: CASI HC A03/MF A01

Object-oriented design principles map well onto protocol implementations because protocols essentially manipulate two structures - packets and the states of the endpoints. In this paper the authors describe an implementation of the Xpress Transfer Protocol as a user space daemon written in C++. The object-oriented model forces the programmer to properly place functionality and information ownership. The model facilitates porting to various platforms and greatly eases the task of building data delivery services. DOE

OVERVIEW OF DATA FUSION WORK FOR LAND ELECTRONIC WARFARE
J. Hooper Oct. 1993 28 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A279829; DREO-TN-93-31) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Electronic warfare (EW) is a land combat function. EW produces tactical intelligence information which, if timely, can affect the outcome of the battle. Automation is required for the EW/intelligence cycle to stay inside the ever-narrowing window of the commander's opportunity to respond to and impact battlefield situations. Data fusion will automate the EW analysis process to provide timely situation assessments. Data Fusion and Correlation Techniques Testbed (DFACTT) is a system designed in Canada to respond to the Canadian EW requirement. It is user verified and field proven. DFACTT is also the vehicle for long term research into the more esoteric

AI aspects of EW analysis including multisensor fusion. DFACTT is made up of a number of workstations which, together, automate the land EW process as practiced by Canada's EW Squadron. DTIC

SYNTHETIC APERTURE RADAR PROCESSING WITH POLAR FORMATTED SUBAPERTURES

Armin W. Doerry 1994 6 p Presented at the 28th Annual Asilomar Conference on Signals, Systems, and Computers, Pacific Grove, CA, 31 Oct. - 2 Nov. 1994
(Contract DE-AC04-94AL-85000)
(DE95-001830; SAND-94-1375C; CONF-9410156-2) Avail: CASI HC A02/MF A01

Synthetic Aperture Radar (SAR) uses the motion of a small real antenna to synthesize a larger aperture, and thereby achieve very fine azimuth resolution. Efficient SAR image formation requires modelling the radar echo and compensating (focusing) the delay and phase for various positions in the target scene. Polar-Format processing is one successful algorithm developed to process large scenes at fine resolutions, but is still limited, especially at resolutions near a wavelength. This paper shows how using tiers of subapertures can overcome the limitations of Polar-Format processing and increase the focused scene size substantially while using only efficient vector multiplies and Fast Fourier Transforms. VIBRATION ANALYSIS OF THE AN/SPS-67(V)3 SURFACE SEARCH RADAR M.S. Thesis

Thomas A. Tomaiko Sep. 1994 131 p
(AD-A286050) Avail: CASI HC A07/MF A02

Modern warships rely greatly upon electronic systems for their combat effectiveness, as well as defense. The ability of the U. S. Navy to maintain sea control and to project sea power depends upon the state-of-the-art combat systems equipment. Shipboard combat systems must, therefore, be shock hardened to be capable of operating in the combat shock environment. The structural survivability of the mast and antennae and hence, the shipboard combat systems, is a shock induced vibration problem in which relatively low frequency equipment responses are observed. The structural survivability of combat systems can be 'designed in' through the application of modern digital techniques for measuring and analyzing dynamic phenomena. The purpose of this study was to build and demonstrate the practical value of a finite element model of the AN/SPS-67(V)3 surface search radar which when validated by experimentally obtained shock qualification data can serve as a powerful tool toward improving survivability of combat systems. The finite element model developed may be used to compute predicted shock-induced accelerations, velocities, displacements, and shock spectra resulting from UNDEX in order to evaluate the potential for antenna structural survivability or vulnerability on an existing platform. Furthermore, the antenna finite element model may be used in the design of new mast-antenna systems. DTIC

CLASSICAL ANALYSIS METHODS FOR DESIGNING AND DEVELOPING DOWNLOOKING RADARS Final Technical Report, Sep. 1992 - Apr. 1994

George Skahill Aug. 1994 96 p
(Contract F30602-92-C-0080)
(AD-A285760; RL-TR-94-113) Avail: CASI HC A05/MF A01

This report describes analytical methods for characterizing the distributions of surface clutter as observed by downlooking radars over spherical planets, taking the classical, pencil and paper, methods of analytic geometry and calculus as far as possible before turning to computer based numerical evaluations. General expressions describing surface clutter power distributions in range and range-rate coordinates are developed in closed form and evaluated for several low PRF, phased array configurations. Information contained in this document formed the subject matter for a series of eight lectures at Rome Laboratory, under this contract, to relative newcomers to the study of clutter limited radar. With the classical analysis tools, they were able to quickly obtain results which compared favorably with those from elaborate simulations evolved by teams of experts over periods of many years. LIDAR TECHNOLOGIES FOR AIRBORNE AND SPACE-BASED APPLICATIONS

Tammy D. Henson, Randal L. Schmitt, Tim J. Sobering, Thomas D. Raymond, and David A. Stephenson Oct. 1994 117 p
(Contract DE-AC04-94AL-85000)
(DE95-002954; SAND-94-0024) Avail: CASI HC A06/MF A02

This study identifies technologies required to extend the capabilities of airborne light detection and ranging (lidar) systems and establish the feasibility of autonomous space-based lidars. Work focused on technologies that enable the development of a lightweight, low power, rugged and autonomous Differential Absorption Lidar (DIAL) instruments. Applications for airborne or space-based DIAL include the measurement of water vapor profiles in support of climate research and processing-plant emissions signatures for environmental and nonproliferation monitoring. A computer-based lidar performance model was developed to allow trade studies to be performed on various technologies and system configurations. It combines input from the physics (absorption line strengths and locations) of the problem, the system requirements (weight, power, volume, accuracy), and the critical technologies available (detectors, lasers, filters) to produce the best conceptual design. Conceptual designs for an airborne and space-based water vapor DIAL, and a detailed design of a ground-based water vapor DIAL demonstration system were completed. Future work planned includes the final testing, integration, and operation of the demonstration system to prove the capability of the critical enabling technologies identified. DOE

THE DEEP SPACE NETWORK AS AN INSTRUMENT FOR RADIO SCIENCE RESEARCH

S. W. Asmar and N. A. Renzetti 15 Apr. 1993 76 p Revised
(Contract NAS7-918; RTOP 314-40-31-30-26)
(NASA-CR-197341; JPL-Publ-80-93-Rev-1; NAS 1.26:197341) Avail: CASI HC A05/MF A01

Radio science experiments use radio links between spacecraft and sensor instrumentation that is implemented in the Deep Space Network. The deep space communication complexes along with the telecommunications subsystem on board the spacecraft constitute the major elements of the radio science instrumentation. Investigators examine small changes in the phase and/or amplitude of the radio signal propagating from a spacecraft to study the atmospheric and ionospheric structure of planets and satellites, planetary gravitational fields, shapes, masses, planetary rings, ephemerides of planets, solar corona, magnetic fields, cometary comae, and such aspects of the theory of general relativity as gravitational waves and gravitational redshift. THREE-DIMENSIONAL EFFECTS FOR RADIO FREQUENCY ANTENNA MODELING
M. D. Carter, D. B. Batchelor, and D. C. Stallings 1993 4 p Presented at the 10th Topical Conference on Radio Frequency Power in Plasmas, Boston, MA, 1-3 Apr. 1993
(Contract DE-AC05-84OR-21400)
(DE94-019125; CONF-9304112-26) Avail: CASI HC A01/MF A01

Electromagnetic field calculations for radio frequency (RF) antennas in two dimensions (2-D) neglect finite antenna length effects as well as the feeders leading to the main current strap. The 2-D calculations predict that the return currents in the sidewalls of the antenna structure depend strongly on the plasma parameters, but this prediction is suspect because of experimental evidence. To study the validity of the 2-D approximation, the Multiple Antenna Implementation System (MAntIS) has been used to perform three-dimensional (3-D) modeling of the power spectrum, plasma loading, and inductance for a relevant loop antenna design. Effects on antenna performance caused by feeders to the main current strap and conducting sidewalls are considered. The modeling shows that the feeders affect the launched power spectrum in an indirect way by forcing the driven RF current to return in the antenna structure rather than the plasma, as in the 2-D model. It has also been found that poloidal dependencies in the plasma impedance matrix can reduce the loading predicted from that predicted in the 2-D model. For some plasma parameters, the combined 3-D effects can lead to a reduction in the predicted loading by as much as a factor of 2 from that given by the 2-D model, even with end-effect corrections for the 2-D model. APPLIED MATHEMATICAL PROBLEMS IN MODERN ELECTROMAGNETICS Final Report, 1 Jun. 1991 - 31 May 1994
Gregory Kriegsman 31 May 1994 15 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Grant AF-AFOSR-0252-91)
(AD-A286448; AFOSR-94-0703TR) Avail: CASI HC A03

We have primarily investigated two classes of electromagnetic problems. The first contains the quantitative description of microwave heating of dispersive and conductive materials. Such problems arise, for example, when biological tissue are exposed, accidentally or purposefully, to microwave radiation. Other instances occur in ceramic processing, such as sintering and microwave assisted chemical vapor infiltration and other industrial drying processes, such as the curing of paints and concrete. The second class characterizes the scattering of microwaves by complex targets which possess two or more disparate length and/or time scales. Spatially complex scatterers arise in a variety of applications, such as large gratings and slowly changing guiding structures. The former are useful in developing microstrip energy couplers while the later can be used to model anatomical subsystems (e.g., the open guiding structure composed of two legs and the adjoining lower torso). Temporally complex targets occur in applications involving dispersive media whose relaxation times differ by orders of magnitude from thermal and/or electromagnetic time scales. For both cases the mathematical description of the problems gives rise to complicated ill-conditioned boundary value problems, whose accurate solutions require a blend of both asymptotic techniques, such as multiscale methods and matched asymptotic expansions, and numerical methods incorporating radiation boundary conditions, such as finite differences and finite elements. METHOD AND APPARATUS FOR CLASSIFYING TARGETS Patent
Roger F. Dwyer, inventor (to Navy) 9 Aug. 1994 14 p Filed 22 Oct. 1993
(AD-D016519; US-Patent-5,337,053; US-Patent-Appl-SN-147238) Avail: US Patent and Trademark Office

A method and apparatus for classifying objects based upon information contained in the fourth order cumulant derived from energy of the object. Successive pulse returns in active systems and samples in passive systems are converted into vectors based upon the fourth order cumulant information for each successive return or sample. The vectors for each such pulse are compared to corresponding class information based upon the corresponding fourth order cumulant information. The comparison uses loglikelihood ratios of the different pairs of classes. Decision making is based upon the value of each loglikelihood ratio in comparison with a class threshold. DTIC

This paper documents the results of a preliminary assessment performed on the commercial off-the-shelf (COTS) Semaphore Communications Corporation (SCC) Network Security System (NSS). The Semaphore NSS is a family of products designed to address important network security concerns, such as network source address authentication and data privacy. The assessment was performed in the INFOSEC Core Integration Laboratory, and its scope was product usability focusing on interoperability and system performance in an existing operational network. Included in this paper are preliminary findings. Fundamental features and functionality of the Semaphore NSS are identified, followed by details of the assessment, including test descriptions and results. A summary of test results and future plans are also included. These findings will be useful to those investigating the use of commercially available solutions to network authentication and data privacy. DTIC

ORBIT DETERMINATION OF HIGHLY ELLIPTICAL EARTH ORBITERS USING IMPROVED DOPPLER DATA-PROCESSING MODES c13
J. A. Estefan *In its* The Telecommunications and Data Acquisition

Report 15 Feb. 1995 p 1-17 (For primary document see N95-21532 06-32)
(RTOP 314-30-11-60-02)
Avail: CASI HC A03/MF A03

A navigation error covariance analysis of four highly elliptical Earth orbits is described, with apogee heights ranging from 20,000 to 76,800 km and perigee heights ranging from 1,000 to 5,000 km. This analysis differs from earlier studies in that improved navigation data-processing modes were used to reduce the radio metric data. For this study, X-band (8.4-GHz) Doppler data were assumed to be acquired from two Deep Space Network radio antennas and reconstructed orbit errors propagated over a single day. Doppler measurements were formulated as total-count phase measurements and compared to the traditional formulation of differenced-count frequency measurements. In addition, an enhanced data-filtering strategy was used, which treated the principal ground system calibration errors affecting the data as filter parameters. Results suggest that a 40- to 60-percent accuracy improvement may be achievable over traditional data-processing modes in reconstructed orbit errors, with a substantial reduction in reconstructed velocity errors at perigee. Historically, this has been a regime in which stringent navigation requirements have been difficult to meet by conventional methods. Author

SEAMLESS DATA-RANGE CHANGE USING PUNCTURED CONVOLUTIONAL CODES FOR TIME-VARYING SIGNAL-TO-NOISE RATIOS

Y. Feria and K.-M. Cheung *In its* The Telecommunications and Data Acquisition Report 15 Feb. 1995 p 18-28 (For primary document see N95-21532 06-32)
(RTOP 314-30-61-02-05)
Avail: CASI HC A02/MF A03

In a time-varying signal-to-noise ration (SNR) environment, symbol rate is often changed to maximize data return. However, the symbol-rate change has some undesirable effects, such as changing the transmission bandwidth and perhaps causing the receiver symbol loop to lose lock temporarily, thus losing some data. In this article, we are proposing an alternate way of varying the data rate without changing the symbol rate and, therefore, the transmission bandwidth. The data rate change is achieved in a seamless fashion by puncturing the convolutionally encoded symbol stream to adapt to the changing SNR environment. We have also derived an exact expression to enumerate the number of distinct puncturing patterns. To demonstrate this seamless rate change capability, we searched for good puncturing patterns for the Galileo (14,1/4) convolutional code and changed the data rates by using the punctured codes to match the Galileo SNR profile of November 9, 1997. We show that this scheme reduces the symbol-rate changes from nine to two and provides a comparable data return in a day and a higher symbol SNR during most of the day. Author

TURBO CODES FOR DEEP-SPACE COMMUNICATIONS

D. Divsalar and F. Pollara *In its* The Telecommunications and Data Acquisition Report 29-39 (SEE N95-21532 06-32) 15 Feb. 1995 (For primary document see N95-21532 06-32)
(RTOP 315-91-20-20-53)
Avail: CASI HC A03/MF A03

Turbo codes were recently proposed by Berrou, Glavieux, and Thitimajshima, and it has been claimed these codes achieve near-Shannon-limit error correction performance with relatively simple component codes and large interleavers. A required E(b)/N(o) of 0.7 dB was reported for a bit error rate of 10(exp -5), using a rate 1/2 turbo code. However, some important details that are necessary to reproduce these results were omitted. This article confirms the accuracy of these claims, and presents a complete description of an encoder/decoder pair that could be suitable for deep-space applications, where lower rate codes can be used. We describe a new simple method for trellis termination, analyze the effect of interleaver choice on the weight distribution of the code, and introduce the use of unequal rate component codes, which yield better performance. Author

CDMA WITH INTERFERENCE CANCELLATION FOR MULTIPROBE MISSIONS

D. Divsalar and M. K. Simon *In its* The Telecommunications and Data Acquisition Report 15 Feb. 1995 p 40-53 (For primary document see N95-21532 06-32)
(RTOP 315-91-20-20-53)
Avail: CASI HC A03/MF A03

Code division multiple-access spread spectrum has been proposed for use in future multiprobe/multispacecraft missions. This article considers a general parallel interference-cancellation scheme that significantly reduces the degradation effect of probe (user) interference but with a lesser implementation complexity than the maximum-likelihood technique. The scheme operates on the fact that parallel processing simultaneously removes from each probe (user) the total interference produced by the remaining most reliably received probes (users) accessing the channel. The parallel processing can be done in multiple stages. The proposed scheme uses tentative decision devices with different optimum thresholds at the multiple stages to produce the most reliably received data for generation and cancellation of probe/spacecraft interference. The one-stage interference cancellation was analyzed for two types of tentative decision devices, namely, hard and null zone decisions. Simulation results are given for one- and two-stage interference cancellation for equal as well as unequal received power probes. Author

COMBINING IMAGE-PROCESSING AND IMAGE COMPRESSION SCHEMES **c61**

H. Greenspan (California Inst. of Tech., Pasadena, CA.) and M.-C. Lee (Microsoft Corp., Redmond, WA.) *In its* The Telecommunications and Data Acquisition Report 15 Feb. 1995 p 54-76 (For primary document see N95-21532 06-32)
(RTOP 315-91-40-20-36)
Avail: CASI HC A03/MF A03

An investigation into the combining of image-processing schemes, specifically an image enhancement scheme, with existing compression schemes is discussed. Results are presented on the pyramid coding scheme, the subband coding scheme, and progressive transmission. Encouraging results are demonstrated for the combination of image enhancement and pyramid image coding schemes, especially at low bit rates. Adding the enhancement scheme to progressive image transmission allows enhanced visual perception at low resolutions. In addition, further progressing of the transmitted images, such as edge detection schemes, can gain from the added image resolution via the enhancement. Author

A METHOD USING FOCAL PLANE ANALYSIS TO DETERMINE THE PERFORMANCE OF REFLECTOR ANTENNAS

P. W. Cramer, W. A. Imbriale, and S. R. Rengarajan (California State Univ., Northridge, CA.) *In its* The Telecommunications and Data Acquisition Report 15 Feb. 1995 p 78-103 (For primary document see N95-21532 06-32)
(RTOP 314-30-11-00-12)
Avail: CASI HC A03/MF A03

Reflector antenna optimization schemes using array feeds have been used to recover antenna losses resulting from antenna distortions and aberrations and to generate contour coverage patterns. Historically, these optimizations have been carried out using the antenna far-field scattered patterns. The far-field patterns must be calculated separately for each of the array feed elements. For large or complex antennas (which include beam-waveguide antennas), the far-field calculation times can be prohibitive. This article presents a method with which the optimization can be carried out in the antenna focal region, where the scattering calculation needs only to be done once independently of the number of the elements in the array. This article also includes the results of a study, utilizing this unique technique, to determine the capabilities and limitations of using array feeds to compensate for gravitational induced losses in large reflector antennas. ON-WAFER, CRYOGENIC CHARACTERIZATION OF ULTRA-LOW NOISE HEMT DEVICES **c33**

J. J. Bautista, J. Laskar (Hawaii Univ., Honolulu, HI.), and P. Szydlik (State Univ. of New York, Plattsburgh, NY.) *In its* The Telecommunications and Data Acquisition Report 15 Feb. 1995 p 104-120 (For primary document see N95-21532 06-32)
(RTOP 314-30-11-10-02)
Avail: CASI HC A03/MF A03

Significant advances in the development of high electron-mobility field-effect transistors (HEMT's) have resulted in cryogenic, low-noise amplifiers (LNA's) whose noise temperatures are within an order of magnitude of the quantum noise limit (hf/k). Further advances in HEMT technology at cryogenic temperatures may eventually lead to the replacement of maser and superconducting insulator superconducting front ends in the 1- to 100-GHz frequency band. Key to identification of the best HEMT's and optimization of cryogenic LNA's are accurate and repeatable device measurements at cryogenic temperatures. This article describes the design and operation of a cryogenic coplanar waveguide probe system for the characterization and modeling of advanced semiconductor transistors at cryogenic temperatures. Results on advanced HEMT devices are presented to illustrate the utility of the measurement system. Author

Avail: CASI HC A03/MF A03

The Radio Science Systems Group (RSSG) provides various support functions for several flight project radio-science teams. Among these support functions are uplink and sequence planning, real-time operations monitoring and support, data validation, archiving and distribution functions, and data processing and analysis. This article describes the support functions that encompass radio-science data performance analysis. The primary tool used by the RSSG to fulfill this support function is the STBLTY program set. STBLTY is used to reconstruct observable frequencies and calculate model frequencies, frequency residuals, frequency stability in terms of Allan deviation, reconstructed phase, frequency and phase power spectral density, and frequency drift rates. In the case of one-way data, using an ultrastable oscillator (USO) as a frequency reference, the program set computes the spacecraft transmitted frequency and maintains a database containing the in-flight history of the USO measurements. The program set also produces graphical displays. Some examples and discussions on operating the program set on Galileo and Ulysses data will be presented. Author

ANALYSIS OF A MICROSTRIP REFLECTARRAY ANTENNA FOR MICROSPACECRAFT APPLICATIONS

J. Huang *In its* The Telecommunications and Data Acquisition Report 15 Feb. 1995 p 153-173 (For primary document see N95-21532 06-32)
(RTOP 315-91-50-20-04)
Avail: CASI HC A03/MF A03

A microstrip reflectarray is a flat reflector antenna that can be mounted conformally onto a spacecraft's outside structure without consuming a significant amount of spacecraft volume and mass. For large apertures (2 m or larger), the antenna's reflecting surface, being flat, can be more easily and reliably deployed than a curved parabolic reflector. This article presents the study results on a microstrip reflect-array with circular polarization. Its efficiency and bandwidth characteristics are analyzed. Numerous advantages of this antenna system are discussed. Three new concepts using this microstrip reflectarray are also proposed. Author

THE EFFICIENCY CALIBRATION OF THE DSS-24 34-METER BEAM-WAVEGUIDE ANTENNA

L. S. Alvarez, M. J. Britcliffe, M. M. Franco, S. R. Stewart, and H. J. Jackson *In its* The Telecommunications and Data Acquisition Report 15 Feb. 1995 p 174-187 (For primary document see N95-21532 06-32)
(RTOP 314-30-63-02-04)
Avail: CASI HC A03/MF A03

Microwave performance testing of the new Deep Space Station (DSS)-24 34-m-diameter antenna was carried out during the summer of 1994. Efficiency measurements were made at the 8.45 GHz (X-band) and 32-GHz (ka-band) frequencies both at the antenna Cassegrian (f1) and beam-waveguide (f3) focal points. In addition, the antenna f3 efficiencies were measured on the DSS-24 operational 2.295-GHz (S-band) and 8.45-Ghz feeds. This article presents the efficiency determinations as a function of elevation angle along with a corresponding error analysis of the measurements. Peak measured gains and efficiencies are tabulated for all frequencies. Author

ANALYSIS OF A DISK-ON-ROD SURFACE WAVE ELEMENT INSIDE A CORRUGATED HORN USING THE MODE-MATCHING TECHNIQUE

J. C. Chen *In its* The Telecommunications and Data Acquisition Report 15 Feb. 1995 p 188-202 (For primary document see N95-21532 06-32)
(RTOP 314-30-11-00-10)
Avail: CASI HC A03/MF A03

A disk-on-rod inside a corrugated horn is one of the horn configurations for dual-frequency or wide-band operation. A mode-matching analysis method is described. A disk-on-rod inside a corrugated horn is represented as a series of coaxial waveguide sections and circular waveguide sections connected to each other. Three kinds of junctions need to be considered: coaxial-to-coaxial, coaxial-to-circular, and circular-to-circular. A computer program was developed to calculate the scattering matrix and the radiation pattern of a disk-on-rod inside a corrugated horn. The software as verified by experiment, and good agreement between calculation and measurement was obtained. The disk-on-rod inside a corrugated horn design gives an option to the Deep Space Network dual-frequency operation system, which currently is a two-horn/one-dichroic plate system. Author

Efforts have been oriented to impact the RASSP program and objectives in two major ways. One is to identify and develop appropriate classes of emerging as well as more classical signal processing algorithms which will exercise and challenge the RASSP tools and process. In this way we would anticipate being able to identify and define in detail signal processing algorithms that are important but that the current tools can't accommodate well. We are currently envisioning doing this with the iterative and PDE algorithms, 'approximate' algorithms, and algorithms oriented toward fault tolerance. The second is for our research to provide specific input for a real or hypothetical next generation of RASSP tools and process. One phase of this, of course, will follow somewhat from our having identified weaknesses in the currently available tools. In addition, we are developing specific paradigms for environments that incorporate symbolic design and processing and approximate processing. Derived from text

SUBSAMPLING METHODS FOR IMAGE SEQUENCE CODING Ph.D. Thesis

R. A. F. Belfor 9 Jun. 1994 146 p
(PB95-107991; ISBN-90-5326-017-X) Copyright Avail: Issuing Activity (National Technical Information Service (NTIS))

Subsampling can be used as a method to compress digital image sequences. The thesis begins with a look at fixed lattice subsampling systems with linear non-adaptive interpolation filters. This system is used to discuss the basics of subsampling. The interpolation process is the only aspect in this subsampling scheme open for improvement. Therefore, some alternatives for the linear non-adaptive interpolation are discussed. The restriction of a fixed subsampling lattice prevents the effective use of all the image characteristics. Thus, adaptive sampling lattices are used instead. First, the sampling lattice is adapted to the local image structure. Then, sub-Nyquist sampling and motion compensated sub-Nyquist sampling is discussed. The problem of combining transform coding with either fixed lattice subsampling or sub-Nyquist sampling is considered. Finally, the different subsampling systems are compared with each other. NTIS

This paper looks into communications capabilities that are required by distributed multimedia applications to achieve relation preserving information exchange. These capabilities are derived by analyzing the notion of 'information exchange' and are embodied in communications functionalities. To emphasize the importance of the users' view, a top-down approach is applied. The revised Open Systems Interconnection (OSI) Application Layer Structure (OSI-ALS) is used to model the communications functionalities and to develop an architecture for composition of multimedia teleservices with these functionalities. This work may therefore be considered an exercise to evaluate the suitability of OSI-ALS for composition of multimedia teleservices. NTIS

BROADBAND PRESSURE BARRIER FOR CIRCULAR WAVEGUIDE Patent Application

David F. Rivera, inventor, Michael J. Josypenko, inventor, and Thomas R. Floyd, inventor 8 Aug. 1994 23 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-D016503; US-Patent-Appl-SN-287023) Avail: Issuing Activity
(Defense Technical Information Center (DTIC))

A broad passband pressure barrier arrangement is provided for insertion in a circular waveguide between a source and a receiver of radio frequency (RF) energy with a spatially circumferential electric field characteristic of the TE 01 mode. At least three abutting cylindrical barrier regions are coaxially aligned and arranged symmetrically in mirror image fashion about a radial plane of the circular waveguide. The cylindrical barrier regions include: at least one solid cylindrical plug region sealed in a cross-section of the circular waveguide and having a longitudinal thickness sufficient to withstand a predetermined pressure load, and at least one solid cylindrical tuning region having a radius less than that of the circular waveguide and further having a longitudinal thickness. Each of the cylindrical barrier regions are defined by a characteristic impedance at opposing end faces thereof and by a characteristic impedance between the opposing end faces. A region-by-region impedance analysis process begins with an end face of the arrangement that is furthest from the source and is completed with an end face of the arrangement that is nearest the source. During April 1992 and September/October 1992, the U.S. Coast Guard R&D Center conducted experiments to determine the sweep width for the AN/APS-137 Forward Looking Airborne Radar (FLAR) when searching for 4-, 6- and 10-person life rafts and small recreational boats. Workboats used to deploy the life rafts during the Fall 1992 experiment were used as targets of opportunity. The experiments were conducted in the coastal waters off the west coast of Florida from Wacussa Bay to Gasparilla Island and on Lake Erie. Realistic radar searches to collect data used unalerted sensor operators and standard search patterns for small waterborne targets. Aircraft and target positions were recorded using a Differential Global Positioning System (DGPS). Target detections were recorded by observers and by computers onboard the aircraft. Environmental conditions were recorded by observers on the workboats. In addition, MINIMET(TM) environmental buoys recorded the sea and wind conditions in the search areas. Environmental conditions represented in the data set included 1.0- to 3.6-foot significant sea heights and 2.9- to 15.2-knot winds. DTIC

ELECTROMAGNETIC RADIATION DETECTOR UTILIZING AN ELECTROMAGNETIC RADIATION ABSORBING ELEMENT IN A MACH-ZEHNDER INTERFEROMETER ARRANGEMENT Patent

Lloyd C. Bobb, inventor (to Navy) 20 Sep. 1994 5 p Filed 30 Sep. 1992
(AD-D016507; US-Patent-5,349,437; US-Patent-Appl-SN-954521;
US-Patent-Class-356-345) Avail: US Patent and Trademark Office

Apparatus is provided to detect electromagnetic radiation, in which a radiation-absorbing element is disposed on a short section of an optical waveguide to provide a thermal interface there between. Radiation is absorbed by the element, which thereby heats the waveguide, causing it to change its optical pathlength in proportion to the radiation absorbed. Interferometer apparatus is connected to measure this change in optical pathlength as a change in the interference condition. This device is highly sensitive and can be operated at room temperature. ELECTROMAGNETIC WAVES IN AN ULTRARELATIVISTICALLY HOT AND STRONGLY MAGNETIZED ELECTRON-POSITRON PLASMA
U. A. Mofiz (Atomic Energy Research Establishment, Dhaka, Bangladesh.) and Ferdous Khan (Atomic Energy Research Establishment, Dhaka, Bangladesh.) Sep. 1993 6 p
(DE94-628963; IC-93/313) Avail: CASI HC A02/MF A01 (US Sales Only)

Electromagnetic waves in an ultrarelativistically hot and strongly magnetized electron-positron plasma is considered. The dispersion formulae for the circularly polarized waves propagating along the ambient magnetic field is obtained. The linear growth (damping) of these modes is calculated and the nonlinear propagation of Alfven mode is investigated. Spiky Alfven solitons are found and its relationship with the pulsar radiation is discussed. DOE

INBAND SCATTERING FROM ARRAYS WITH SERIES FEED NETWORKS Final Report
Seunghoon Lee Sep. 1994 50 p
(AD-A286209) Avail: CASI HC A03/MF A01

Approximate formulas for the inband radar cross section (RCS) of an array with series feed have been derived. The formulas are based on the hypothesis that an incident wave excites forward and backward traveling waves on the main line. The approximate formulas are in good agreement with results obtained using scattering matrices, thereby verifying the assumptions made in the approximate solution. Spikes in the RCS pattern have been identified with specific scattering sources in the array. The parameters affecting the level and location of the lobes have been noted. The main advantage of the approximate method relative to the scattering matrix method is its speed. The scattering matrix method requires that a matrix equation be solved, and its size increases with the number of array elements. DTIC

COCHANNEL AND ADJACENT-CHANNEL INTERFERENCE IN NONLINEAR MINIMUM-SHIFT-KEYED SATELLITE SYSTEM
John Yu Mar. 1995 9 p
(RTOP 235-01-03)
(NASA-TM-106834; E-9395; NAS 1.15:106834) Avail: CASI HC A02/MF A01

The interference susceptibility of a serial-minimum-shift-keyed (SMSK) modulation system to an interfering signal transmitted through a satellite link with cascaded nonlinear elements was investigated through computer simulation. The satellite link evaluated in this study represented NASA's Advanced Communications Technology Satellite (ACTS) system. Specifically, nonlinear characteristics were used that had specified amplitude-modulation to amplitude-modulation and amplitude-modulation to phase-modulation transfer characteristics obtained from the actual ACTS hardware. Two measurement scenarios were analyzed: degradation of an MSK satellite link from cochannel interference and from adjacent-channel interference. Interference was evaluated in terms of the probability of bit error rate (BER) versus energy per bit over noise power density Eb/No. Author

FREQUENCY-CODED MONOPULSE MTI Patent
Bernard L. Lewis, inventor (to Navy) and Ben H. Cantrell, inventor (to Navy) 13 Sep. 1994 7 p Filed 23 Jul. 1976
(AD-D016495; US-Patent-5,347,281; US-Patent-Appl-SN-707465; US-Patent-Class-342-160) Avail: US Patent and Trademark Office

A pulse-compression, MTI, doppler-radar system for determining target velocity information from a single, frequency-coded uncompressed target-return pulse includes a coded modulator, two pulse compressors, and a phase-comparison processor. The coded modulator generates for transmission an uncompressed pulse with the first and second halves of the pulse coded with the even and odd harmonic sidebands of a pulse repetition frequency, respectively. The first and second halves of the pulse returning from the target are pulse compressed simultaneously by the two pulse compressors. The phase comparison processor then determines the phase difference between the compressed pulses to obtain the target velocity information. DTIC

DIRECTIVE OPTIMIZATION OF COHERENT SIDELOBE CANCELLER SYSTEMS Patent
James P. Hansen, inventor (to Navy) 27 Sep. 1994 5 p Filed 25 Nov. 1974
(AD-D016513; US-Patent-5,351,057; US-Patent-Appl-SN-528194; US-Patent-Class-342-378) Avail: US Patent and Trademark Office

A new technique is introduced for improving the operation of a interference suppression system, particularly in a side-lobe canceller system, against multiple interference sources. A plurality of auxiliary receiving antennas, providing interference signals to side-lobe canceller loops, are spaced about a main directional receiving antenna and positioned to preferably form a configuration such that no lines of sight through any two auxiliary antennas are collinear or parallel to a line of sight through any other two auxiliary antennas. The configuration is then arranged relative to the main antenna such that no lines through any two auxiliary antennas are substantially parallel with the primary direction of a multiple jammer attack. PASSIVE SURFACE DEPLOYED VARIABLE INDUCTANCE WIRE ANTENNA STATEMENT OF GOVERNMENT INTEREST Patent Application
Paul Mileski, inventor (to Navy) 4 Oct. 1993 12 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-D016210; US-Patent-Appl-SN-130941) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

An antenna adapted for surface deployment is provided. A coaxial feedline, terminated at one end thereof at a feedpoint, has a center conductor and a shield at ground potential. A continuous length of antenna wire having first and second ends is electrically connected at its first end to the center conductor at the feedpoint. A first portion of the continuous length is spooled adjacent to the first end. A second portion of the continuos length is deployed from the first portion by means of tension at the second end. The second portion extends to the second end along a substantially straight line away from the first portion. The second portion is typically at least as long as the first portion. The first portion serves as a variable tuning inductor for the antenna as the second portion is deployed therefrom. DTIC

ATOMIC VELOCITY DISTRIBUTIONS IN A HYDROGEN BEAM EFFUSING OUT OF AN RF DISCHARGE DISSOCIATOR
B. Jaduszliwer and Y. C. Chan 15 Mar. 1994 19 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract F04701-88-C-0089)

(AD-A279253; TR-93(3925)-6; SMC-TR-99-22) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

We have measured atomic hydrogen velocity distributions in an effusive beam coming out of an RF discharge dissociator by using a magnetic deflection technique. Dissociator pressures varied between 0.028 and 0.340 torr. At low dissociator pressures, the measured atomic velocity distributions were narrower than the expected beam-Maxwellians; at higher pressures, they were indistinguishable from beam-Maxwellians at the dissociator wall temperature, indicating full thermalization of the atoms prior to exiting the dissociator. Monte Carlo simulations of the thermalization process within the dissociator reproduce these results and point out the important role of vibrational excitation of the background hydrogen molecules as an energy loss mechanism. Our results are significant when designing magnetic state selectors for spin- or hyperfine-polarized atomic hydrogen beams. DTIC

COMPILATION OF 1993 ANNUAL REPORTS OF THE NAVY ELF COMMUNICATIONS SYSTEM ECOLOGICAL MONITORING PROGRAM. VOLUME 2: TABS C-F Report, Jan. - Sep. 1993

J. E. Zapotosky Apr. 1994 214 p See also AD-A279771

(Contract N00039-93-C-0001)

(AD-A279770; D06209-2-Vol-2) Avail: CASI HC A10/MF A03

During 1993, the U.S. Navy continued to conduct a program to monitor flora, fauna, and their ecological relationships for possible effects from electromagnetic (EM) fields produced by the Navy's Extremely Low Frequency (ELF) Communications System. Physiological, developmental, behavioral, and ecological variables for dominant biota in upland and riverine habitats near the Naval Radio Transmitting Facility at Republic, Michigan (NRTF-Republic) have been monitored since 1982. The NRTF-Republic was intermittently energized at low amperages beginning in early 1986. Electric current and periods of energization were then gradually increased until 1989, when the transmitter became a fully operational facility. A split-plot or blocked strategy was used to examine biological variables for possible effects from EM exposure. Reports compiled in this document present the progress of these studies through 1993. Final results and conclusions are expected after all data have been analyzed in 1994. Investigators for similar studies completed in Wisconsin concluded that there were no EM bioeffects from intermittent or full operation of the transmitter in that state. DTIC

RECOMMENDATION ON TRANSITION FROM PRIMARY/SECONDARY RADAR TO SECONDARY-ONLY RADAR CAPABILITY Final Report, Sep. 1993 - Mar. 1994

Janis Vilcans and Richard J. Lay Oct. 1994 137 p

(AD-A286279; DOT-VNTSC-FAA-94-10; DOT/FAA/NR-94-1) Avail: CASI HC A07/MF A02

This recommendation has been prepared to support the FAA decision to deactivate primary long-range radars (LRR) and presents transition strategy and implementation plan for the transformation of the existing primary/secondary en route radar system to a beacon-only system by the year 2002. The estimated cost associated with this transition is $2.1 billion, but the cost directly related to the decision is approximately $138.6 million. Thus, the potential saving of approximately $1.4 billion associated with LRR replacement results in a benefit-to-cost ratio greater than 10. It is therefore recommended that the decision to deactivate the LRR be implemented as rapidly as possible in order to minimize costs necessary to sustain and maintain the existing system; that an orderly transition be accomplished; and that the transition to the beacon-only capability be adopted on a center-by-center basis. It is also recommended that the goal of an en route beacon system, comprising stand-alone beacon radars and backed up with an automatic dependent surveillance (ADS) system be established, but achievement of this goal should not delay implementation of the deactivation decision. DTIC

SIGNAL PROCESSING IN THE LINEAR STATISTICAL MODEL Final Report, 1 Oct. 1991 - 30 Sep. 1994

Louis L. Scharf and Clifford T. Mullis 4 Nov. 1994 10 p

(Contract N00014-89-J-1070)

(AD-A286255) Avail: CASI HC A02/MF A01

This report summarizes work on four general problems during the three-year period of the contract: (1) estimation of frequency-wavenumber, (2) matched subspace filters, (3) maximum likelihood estimation of modes from space-time data, and (4) statistical inference within the wavelet representation. We have generalized the theory of multiwindow estimators of the power spectrum to multiwindow estimators of the frequency wavenumber spectrum and of the related correlation sequence. We are now applying these ideas to the derivation of adaptive filters. We have developed a theory of matched subspace detectors for detecting signals which lie in low-dimensional model subspaces. The theory bridges the gap between generalized likelihood ratio theories and invariance theories. We have generalized the theory of maximum likelihood for identifying time domain modes and space domain directions of arrival. We have characterized subband decompositions for perfect reconstruction, developed filter design algorithms for constructing near perfect reconstruction filterbanks from nonorthogonal analysis filters, and derived algorithms for predicting and filtering in periodically correlated time series. MODELLING MULTIMEDIA TELESERVICES WITH OSI UPPER LAYERS FRAMEWORK: SHORT PAPER

I. Widya, E. vanRijssen, and E. Michiels 1994 12 p

(PB95-132734; Memo-INF-94-40) Copyright Avail: Issuing Activity (National Technical Information Service (NTIS))

The paper presents the use of the concepts and modelling principles of the Open Systems Interconnection (OSI) upper layers structure in the modelling of multimedia teleservices. It puts emphasis on the revised Application Layer Structure (OSI/ALS). OSI/ALS is an object based reference model which intends to coordinate the development of application oriented services and protocols in a consistent and modular way. It enables the rapid deployment and integrated use of these services. The paper emphasizes further on the nesting structure defined in OSI/ALS which allows the design of scalable and user tailorable/controllable teleservices. OSI/ALS consistent teleservices are moreover implementable on communication platforms of different capabilities. An analysis of distributed multimedia architectures which can be found in the literature, confirms the ability of the OSI/ALS framework to model the interworking functionalities of teleservices. One way of providing connectionless services over an asynchronous transfer mode (ATM) network is by means of Connectionless Servers (CLS's), routing and forwarding cells on a per packet basis (message mode). Packets are sent to a CLS over ATM connections (either virtual channel or virtual path connections). These packets come from other CLS's, interworking units, or end systems. The CLS stores cells of a packet in a reassembly buffer until the last one has been received, and forwards all cells of the packet at once. We present a performance model of the reassembly buffer in a CLS operating in message mode. NTIS

LADAR DETECTION STATISTICS IN THE PRESENCE OF POINTING ERRORS
Hal T. Yura 15 Dec. 1993 69 p
(Contract F04701-88-C-0089)
(AD-A285865; TR-93(3505)-1; SMC-TR-94-39) Avail: CASI HC A04/MF A01

The probability of detection of optically rough targets by pulsed LADAR systems that employ direct detection is considered here. It is assumed that the LADAR operates under conditions of both unintentional pointing off-set bias (i.e., bore-sight error) and jitter. Under these conditions, the probability of detection of targets in both the near and far field of the collecting aperture (i.e., for resolved, partially resolved, and unresolved targets) and for both large and small photoelectron counts is derived, and, in many cases of practical interest, accurate, elementary analytic approximations that are useful for parametric system studies are obtained. As such, the approximate engineering expressions derived here will be useful, for example, to those performing engineering modeling of space-based LADAR systems. A number of appendices are included to serve as technical references, where some key results employed in the main body of the report are derived. In particular, an interesting new mathematical result involving the complementary incomplete gamma function and an analytic expression for the probability distribution function of a signal photocount obeying Bose-Einstein statistics (such as that arising from unresolved targets) immersed in Poisson noise are derived. DATA SAMPLING FOR A BURST MODE COMMUNICATIONS SYSTEM
A. G. Rocco 1 Sep. 1994 44 p
(Contract F19628-90-C-0002)
(AD-A286098; MIT-TR-1012) Avail: CASI HC A03/MF A01

A data sampling circuit and method is provided for a burst mode communication system. The circuit is an entirely digital circuit for reliably sampling an incoming stream of data to automatically adjust to variations in data stream clock rates and phase variations in the incoming data. The circuit includes a delay line with a plurality of serially coupled taps, each tap having a variable delay. One aspect of the invention includes increasing the delay time until the delay line captures at least one, but preferably two, full data cells of the incoming data stream (i.e., signal levels over at least one full clock period, defined by two transitions of the data stream), thereby aligning the receiving circuit with the frequency of the data stream clock. A second aspect of the invention includes outputting data from a tap that is selected to be midway between two regions of transitions of the incoming data stream, thereby aligning the receiving circuit with the phase of the data stream clock. The invention can, in alternative embodiments, track changes in the input data stream's phase/frequency. This involves updating the amount of delay in each tap of the delay line as well as picking the output of the appropriate tap to be used as the sampled data stream in response to changes in the input signal as well as changes in propagation delays of the circuits used to implement the delay line, resulting from temperature and voltage variations. THE APPLICABILITY OF NEURAL NETWORKS TO IONOSPHERIC MODELING IN SUPPORT OF RELOCATABLE OVER-THE-HORIZON RADAR M.S. Thesis
James A. Pinkepank Sep. 1994 44 p
(AD-A286114) Avail: CASI HC A03/MF A01

Ionospheric models have been developed to interpret Relocatable Over-the-Horizon Radar data. This thesis examines the applicability of neural networks to ionospheric modeling in support of Relocatable Over-the-Horizon Radar. Two neural networks were used for this investigation. The first network was trained and tested on experimental ionospheric sounding data. Results showed neural networks are excellent at modeling ionospheric data for a given day. The second network was trained on ionospheric models and tested on experimental data. Results showed neural networks are able to learn many ionospheric models and the modeling network generally agreed with the experimental data. DTIC

X-BAND MICROWAVE BACKSCATTERING FROM OCEAN WAVES
P. H. Y. Lee (TRW, Inc., Redondo Beach, CA.), J. D. Barter (TRW, Inc., Redondo Beach, CA.), and K. L. Beach (TRW, Inc., Redondo Beach, CA.) Jan. 1994 53 p Presented at the IGARSS 1994: International Geoscience and Remote Sensing Symposium, Pasadena, CA, 8-12 Aug. 1994 Submitted for publication
(Contract W-7405-eng-48)
(DE94-016719; UCRL-CR-117680; CONF-940814-3) Avail: CASI HC A04/MF A01

Backscattering experiments at microwave frequencies were conducted off the west coast of Scotland in the summer of 1991. Using a dual-polarization, 8-frequency X-band coherent scatterometer mounted on the bow of a boat, we measured time-resolved backscattering from ocean waves at a range of grazing angles from 10 deg to 70 deg. From the grazing-angle-dependent signals and their Doppler spectra, we differentiate Bragg scattering from non-Bragg scattering and resolve 'peak separation' between the vertical and horizontal polarizations. We observe instances of 'super' events, i.e., instances when the horizontal polarization return power equals or exceeds the vertical polarization power. We find that 'super' events occur not only at low grazing angles but at any grazing angle for against-wind viewing directions. Statistics for such occurrences as a function of grazing angle are obtained. We study the coherence properties of scatterers and find strong evidence that at low grazing angles, lifetime-dominated, non-Bragg scattering contributes noticeably to returns of both polarizations, but is dominant in providing returns for the horizontal polarization. We examine 'spiking' events and find that they can be related to, but need not be limited to, breaking wave events. By comparing the data of against-wind runs with cross-wind and circle runs, we obtain wind-direction dependence of Doppler spectra which further assists in the identification of scattering mechanisms. DESIGN AND MODELLING OF A LINK MONITORING MECHANISM FOR THE COMMON DATA LINK (CDL) M.S. Thesis
John W. Eichelberger, III Sep. 1994 257 p
(AD-A286167) Avail: CASI HC A12/MF A03

The Common Data Link (CDL) is a full duplex, point-to-point microwave communications system used in imagery and signals intelligence collection systems. It provides a link between two remote Local Area Networks (LAN's) aboard collection and surface platforms. In a hostile environment, there is an overwhelming need to dynamically monitor the link and thus, limit the impact of jamming. This work describes steps taken to design, model, and evaluate a link monitoring system suitable for the CDL. The monitoring system is based on features and monitoring constructs of the Link Control Protocol (LCP) in the Point-to-Point Protocol (PPP) suite. The CDL model is based on a system of two remote Fiber Distributed Data Interface (FDDI) LAN's. In particular, the policies and mechanisms associated with monitoring are described in detail. An implementation of the required mechanisms using the OPNET network engineering tool is described. Performance data related to monitoring parameters is reported. Finally, integration of the FDDI-CDL model with the OPNET Internet model is described. DTIC

PERFORMANCE OF A FAST FREQUENCY-HOPPED NONCOHERENT MFSK RECEIVER OVER RICIAN FADING CHANNELS WITH EITHER PARTIAL-BAND INTERFERENCE OR MULTI-TONE INTERFERENCE M.S. Thesis

Joseph F. Sheltry Sep. 1994 102 p
(AD-A286168) Avail: CASI HC A06/MF A02

An error probability analysis is performed for a conventional noncoherent M-ary orthogonal frequency-shift keying (MFSK) receiver employing fast frequency-hopped (FFH) spread spectrum waveforms transmitted over a frequency-nonselective, slowly fading Ricean channel with partial-band noise interference. Each diversity reception is assumed to fade independently. The partial-band interference is modeled as a Gaussian process. The effects of wideband thermal noise are also included. The energy per hop is held constant; thus, as diversity increases, energy per symbol increases. Previous analyses considered only constant energy per symbol systems, however, practical military systems are likely to employ fixed hop rates. There is some performance enhancement to be obtained from implementing diversity in a conventional FFH/MFSK system with fixed hop rates, but partial band interference still results in significant degradation. Additionally, the performance of this FFH receiver is investigated over the same channel in the presence of partial-band tone jamming without diversity for the case of binary frequency-shift keying (BFSK) when both the signal and the jammer can fade independently. Performance when only a single jamming tone per hop slot is allowed is compared to that obtained when two jamming tones per hop slot are possible. When the jamming signal experiences Rayleigh fading there is very little degradation of the jammer's effectiveness as compared to when the jamming signal is not affected by fading. DTIC

INVERSE AND CONTROL PROBLEMS IN ELECTROMAGNETICS Final Report, 1 Jul. 1991 - 30 Jun. 1994

Ralph E. Kleinman and Thomas S. Angell 14 Oct. 1994 255 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Grant AF-AFOSR-0277-91)
(AD-A286438; AFOSR-94-0743TR) Avail: CASI HC A12

This report summarizes work carried out in a number of specific areas of investigation in inverse scattering and optimal control problems in electromagnetics. The progress is briefly described and detailed results are included in an appendix. The major accomplishments include: the application of multi-criteria optimization techniques to problems in antenna design; the development of inverse scattering algorithms which use scattered field data in the frequency domain to reconstruct the shape, location and constitutive parameters of a scattering object; establishing the well-posedness of electromagnetic scattering problems with resistive or conductive boundary conditions; and derivation of new boundary integral equations for electromagnetic scattering from local distributions of a plane screen. In addition some new results on low frequency scattering have been found which establish the exact nature of the asymptotic expansion in two dimensions. DTIC

PROBABILITY OF DETECTION FOR A GO CFAR RADAR PROCESSOR USING ENVELOPE DETECTION APPROXIMATION M.S. Thesis

Joseph J. Hache Sep. 1994 139 p
(AD-A286211) Avail: CASI HC A07/MF A02

The greatest-of logic for a constant false alarm rate processor (GO CFAR) is a commonly used method for the adaptive setting of a radar detection threshold in the presence of clutter edges. Instead of using a true envelope detector x = I2 + Q2, which is difficult to implement, envelope detection approximations of the form Xe = aMax (I),(Q) + bMin (I),(Q) and xe = a(I) + b(Q) (no Max and Min operators) where a and b are constants, are often used to detect a signal decomposed into its in-phase (I) and quadrature (Q) components. Closed form expressions are derived for the probability density function (pdf) of a radar range cell containing a detected target signal in the presence of noise using both approximations. These can then be used to calculate the probability of detection (PD). They can also be used to calculate the probability of false alarm (PFA) if the means of I and Q are set to zero. Closed form expressions are obtained analytically and by curve-fitting the numerically derived pdf of the target cell. Finally, using Monte Carlo techniques, this thesis also compares the GO CFAR detection performance using envelope detection approximations xe, xe and the true envelope detector x for zero mean white Gaussian noise input samples I and Q. CALIOPE AND TAISIR AIRBORNE EXPERIMENT PLATFORM

C. J. Chocol Jul. 1994 11 p Presented at the 1994 Chemical Analysis by Laser Interrogation of Proliferation Effluents (CALIOPE ITR) Interim Technical Review, Livermore, CA, 26-28 Apr. 1994
(Contract W-7405-eng-48)
(DE94-018328; UCRL-JC-118289; CONF-9404162-10) Avail: CASI HC A03/MF A01

Between 1950 and 1970, scientific ballooning achieved many new objectives and made a substantial contribution to understanding near-earth and space environments. In 1986, the Lawrence Livermore National Laboratory (LLNL) began development of ballooning technology capable of addressing issues associated with precision tracking of ballistic missiles. In 1993, the Radar Ocean Imaging Project identified the need for a low altitude (1 km) airborne platform for its Radar system. These two technologies and experience base have been merged with the acquisition of government surplus Aerostats by Lawrence Livermore National Laboratory. The CALIOPE and TAISIR Programs can benefit directly from this technology by using the Aerostat as an experiment platform for measurements of the spill facility at NTS. DOE

IMAGE SOLUTION FOR POISSON'S EQUATION IN WEDGE GEOMETRY

K. I. Nikoskinen and I. V. Lindell Apr. 1994 25 p
(PB95-127171; ISBN-951-22-2094-6) Avail: CASI HC A03/MF A01

Recently a novel static solution appeared for two-dimensional electrostatic field excited by an infinite line charge in the vicinity of a dielectric wedge whose edge was parallel to the source. In the present paper Poisson's equation is studied mainly in three dimensions but the solution for the analog two dimensional problem is also provided. It appears that numerically a simple and efficient method to compute the potential inside and outside the wedge can be found by solving first image sources for the exterior and interior problem that give rise to the potential contribution of the wedge. Both the exterior and interior consist of a line charge that decays exponentially as a function of complex angle and a set of point charges that can be interpreted as a reflection or transmission images of a dielectric plane. All known closed-form solutions in terms of elementary functions are derived for an electrically and magnetically conducting half plane. NTIS

IMAGE AND VIDEO CODING USING A WAVELET DECOMPOSITION Ph.D. Thesis
H. J. Barnard 1994 222 p
(PB95-135067; ISBN-90-5326-016-1) Copyright Avail: Issuing Activity (National Technical Information Service (NTIS))

The thesis discusses the recently developed wavelet theory with respect to its application to image and video coding. The purpose is to evaluate what this theory has contributed to the already existing subband coding method. Further, a new image coding technique is presented that can be viewed as a combination of the wavelet transform and a contour-texture coding technique. The coding performance of the new method is compared to existing methods. NTIS

DIELECTRIC MIXTURES WITH ARBITRARILY ANISOTROPIC COMPONENTS: FOCUS ON SPECIAL GYROTROPIC EFFECTS
A. H. Sihvola and O. P. M. Perkonen Apr. 1994 27 p
(PB95-127015; ISBN-951-22-2051-2) Avail: CASI HC A03/MF A01

The report studies the dielectric properties of mixtures with components that can have arbitrary permittivity dyadic. The anisotropic inclusions are assumed spherical. In the analysis, quasistatic approach is used, and it leads to the general Maxwell Garnett formula. This is represented in many forms, and depending on the orientation distribution of the inclusions, effective permittivity can be dyadic or scalar. Special emphasis is on the case of random orientation of the inclusions. The macroscopic permittivity depends on seven parameters of the mixture, six coming from the symmetric and antisymmetric parts of the inclusion permittivity dyadic, and one from the volume fraction. Numerical illustrations focus on the gyrotropy effects that are shown to lead to sharp maxima and minima in the polarizabilities and macroscopic permittivities. NTIS

IMAGE THEORY FOR THE UNIDIRECTIONALLY CONDUCTING SCREEN
I. V. Lindell Jun. 1994 11 p
(PB95-127031; ISBN-951-22-2184-5) Avail: Issuing Activity (National Technical Information Service (NTIS))

Image theory is developed for electromagnetic sources in front of a planar unidirectionally conducting screen made of ideally conducting parallel wires with thickness and interspace dimensions much smaller than the wavelength. Replacing the screen by the image sources gives the correct reflected and transmitted fields on the respective sides of the screen. The problem is solved through a decomposition of the original source in two parts giving rise to fields TE and TM with respect to the direction of the wires. For the TE and TM source components, the images can be constructed from previous knowledge. For an electric dipole source, the images are seen to involve dipole and transmission-line sources. NTIS

(Contract F19628-91-K-0013)
(AD-A285789; RL-TR-94-172) Avail: CASI HC A05/MF A01

In this final report, we summarize the approach used and relevant information for simulation of radar signal statistics from randomly rough surfaces. The total number of cases to be performed in this contract is 60 and is depicted in Table 1. Two sets of cases reported in the past are: (1) 30 cases for receiver orientation angles of 135 degrees, five azimuthal angles, three cell sizes with signal distributions expressed in both field amplitude and power; and (2) 12 cases for receiver orientation angle of 45 degrees at azimuthal angles of 180 and 135 degrees, three cell sizes with signal distributions expressed in both field amplitude and power. Additional calculations to be given in this report are for receiver orientation angle of 45 degrees at azimuthal angles of 90, 45, and 0 degrees corresponding to 18 cases. For the sake of completeness, all results reported earlier are included in Appendix B. DTIC

TDX: A HIGH-BANDWIDTH CROSSBAR-SWITCHED COMMUNICATION PARADIGM
P. E. Pierce, D. L. Eilers, and A. L. Schreiber 1994 6 p Presented at the ICSPAT 1994: Signal Procession Applications and Technology, Dallas, TX, 18-21 Oct. 1994
(Contract DE-AC04-94AL-85000)
(DE94-017187; SAND-94-1075C; CONF-9410164-4) Avail: CASI HC A02/MF A01

Digital signal processing systems under development today require scalable and reconfigurable high bandwidth communication resources between processing elements. Shared memory architectures require the ability to transfer data from one processor node to another, as well as maintaining data coherency such as provided by the Scalable Coherent Interface (SCI). Signal processing systems that must move large amounts of data between processor nodes, are best served by a communication system that allows reconfigurable streams of data to flow at deterministic rates with minimal overhead. A Time Domain Crossbar (TDX) communication system providing scalable, programmable, high-bandwidth, streaming communication has been developed and is described in this paper. DOE

A PERIODIC SCHEDULING HEURISTIC FOR MAPPING ITERATIVE TASK GRAPHS ONTO DISTRIBUTED MEMORY MULTIPROCESSORS M.S. Thesis
Charles Darwin Kasinger Sep. 1994 52 p
(AD-A286047) Avail: CASI HC A04/MF A01

This thesis investigates the problem of statically assigning the tasks of applications represented by repetitive task graphs (such as sonar or radar signal processing) to the processors of a distributed memory multiprocessor system with the objective of maximizing graph instance throughput. The repetitive nature of these task graphs allows for pipelining and the overlapping of successive graph instances, suggesting a departure from classical directed acyclic graph scheduling techniques. To investigate such a claim, a version of the Mapping Heuristic (MH) ELR 90 is extended for use with iterative applications. Then a new heuristic, Periodic Scheduling (PS), is developed to capitalize on the repetitive nature of these task graphs by overlapping successive graph instances. The PS heuristic assigns tasks to processors in such a way so as to minimize the maximal utilization of the processors and the communications links between them. This maximal utilization figure dictates the interval between successive instances of the task graph. We conduct experiments in which the graph instance throughput of PS is compared to that of MH across a broad range of processor topologies, utilizing several communications/computation ratios. It is shown that, compared to MH, the PS heuristic improves the throughput performance between two and 50 percent. Particularly noteworthy improvement is noted on systems with high average inter-node communications costs. DTIC

PROCESSING, FABRICATION, AND DEMONSTRATION OF HTS INTEGRATED MICROWAVE CIRCUITS Research and Development Status Report No. 12, 25 Apr. - 24 Jul. 1994

G. R. Wagner, S. H. Talisa, and J. Talvacchio 29 Sep. 1994 138 p
(Contract N00014-91-C-0112; ARPA Order 7932)
(AD-A285611; Rept-94-9SL2-LAFIL-R1) Avail: CASI HC A07/MF A02

High temperature superconductor (HTS) devices can and will improve the performance of ESM and shared aperture receiver systems. For the near term the most promising candidate for the reference channelized cued ESM receiver system is an HTS IF Delsy line that can provide 200 nanoseconds of delay across a 3 to 5 GHz band. Such a delay line can improve sensitivity by 1 to 2 dB while providing about a 6 dB improvement in two tone dynamic range. Perhaps even of greater importance is that the low device loss combined with the elimination of multiple amplifiers previously needed to overcome loss can significantly improve the amplitude and phase tracking of the delay lines. In future systems it is unlikely that a single HTS device will be employed. Rather, it is more likely that large portions of the RF architecture will be placed in a cooler as a means of achieving performance and cost advantages. This is thought to include an HTS front-end, conventional IF amplifier, and HTS IF receivers. Looking even further in the future it is likely that entire HTS receivers will be remotely located with their HTS antennas and only digits will be returned to central for processing. DTIC

DESIGN OF POWER ELECTRONICS FOR TVC AND EMA SYSTEMS Final Report

R. Mark Nelms, J. Brett Bell, and Michael T. Shepherd 7 Nov. 1994 41 p
(Contract NAS8-39131)
(NASA-CR-196540; NAS 1.26:196540) Avail: CASI HC A03/MF A01

The Component Development Division of the Propulsion Laboratory at Marshall Space Flight Center (MSFC) is currently developing a class of electromechanical actuators (EMA's) for use in space transportation applications such as thrust vector control (TVC) and propellant control valves (PCV). These high power servomechanisms will require rugged, reliable, and compact power electronic modules capable of modulating several hundred amperes of current at up to 270 volts. MSFC has selected the brushless dc motor for implementation in EMA's. A previous project performed by Auburn University examined the use of the resonant dc link (RDCL) inverter, pulse density modulation (PDM), and mos-controlled thyristors (MCT's) for speed control of a brushless dc motor. The speed of the brushless dc motor is proportional to the applied stator voltage. In a PDM system, the control system determines the number of resonant voltage pulses which must be applied to the stator to achieve a desired speed. The addition of a waveshaping circuit to the front end of a standard three-phase inverter yields a RDCL inverter; the resonant voltage pulses are produced through the action of this wave shaping circuit and the inverter. This project has focused on the implementation of a system which permits zero-voltage switching with the bus voltage clamped at the input voltage level. In the same manner as the RDCL inverter, the inverter selected for this implementation is a combination of waveshaping circuit and a standard three-phase inverter. In addition, this inverter allows a pulse-width modulated (PWM)-like control scheme instead of a PDM scheme. The operation of waveshaping circuit will be described through analysis and waveforms. Design relationships will also be presented. Derived from text

PHYSICAL Si(1-x)Ge(x)/Si HETEROJUNCTION BIPOLAR TRANSISTOR MODEL FOR DEVICE AND CIRCUIT SIMULATION

M. Andersson, Z. Xia, P. Kuivalainen, and H. Pohjonen 1994 26 p
Prepared in cooperation with Helsinki Univ. of Technology, Espoo, Finland
(ISSN 0355-5712)
(PB95-110896; ISBN-951-22-2154-3) Avail: CASI HC A03/MF A01

A physical but compact Si(1-x)Ge(x)/Si heterojunction bipolar transistor (HBT) model suited for device design and circuit simulation is presented. The model is based on the de Graaf-Kloosterman formalism for the modeling of the bipolar transistors, but adds important heterostructure device physics as well as physical properties of SiGe material. The model, implemented in the APLAC circuit simulator, shows how currents and charges depend on minority carrier concentrations, which in turn are functions of the heterojunction voltages. In this way the influence of the built-in electric fields due to Ge concentration and doping density gradients, the bias-dependent transit times and the Early effect can be incorporated naturally. Comparisons between the model prediction and the experimental data for the DC current/voltage characteristics and cutoff frequencies in Si(1-x)Ge(x)/Si HBT's are included to demonstrate the model utility and accuracy. HIGH-PERFORMANCE PACKET SWITCHING ARCHITECTURE FOR ATM: CONVENTIONAL SOLUTION AND NEURAL NETWORK SOLUTION Ph.D. Thesis

J. Ma Feb. 1994 93 p
(PB95-110920; ISBN-951-22-2146-2) Avail: CASI HC A05/MF A01

The thesis consists of two subjects in a high performance packet switch: the first subject is a conventional solution for design, implementation and performance analysis of an Asynchronous Transfer Mode (ATM) modular switch, and the second subject is a neural network application in a high performance packet switch. The first subject covers the following topics: The design of a modular ATM switch is considered. Two modular switch architectures have been proposed: Nonuniform traffic effect on the switch has been investigated; since services require different quality of service, an ATM switch must be capable of handling the requirements of different services. The second subject covers the following topics: The rearrangeable Clos' packet switch has especially attractive advantage in a nonblocking interconnection with less hardware than a nonblocking network can be realized. In addition, the output queuing rearrangeable Clos' switch proposed in this thesis has the best delay/throughput performance. In the thesis the equations of the neural network for the routing problem have been developed, while simulations of the neural networks have been carried out in computers. NTIS

COLLOCATED TUNABLE WAVENUMBER SENSOR/ACTUATORS FOR SMART STRUCTURES Report, 1 Sep. - 30 Sep. 1993

K. Bridger and L. Jones 6 Oct. 1993 4 p
(Contract N00014-92-C-0214)
(AD-A279608; MML-TM-93-23) Avail: CASI HC A01/MF A01

The first actuator module delaminated during burnout. The module showed evidence (bulging) of pressure build up internally which is usually caused by too rapid burnout schedule. The next module is being fabricated and will be in burnout by the end of this week. The pad of smaller actuators look good and are terminated ready for testing. Plans for September 1993; Electromechanical measurements will be on the first set of small actuator, Electromechanical modelling on the actuators will be conducted. Two actuator module iterations will be conducted. One will use a burnout profile based on a conventional (100-mg sample size) thermogravimetric analysis result; the other will be in a specially rigged furnace to monitor temperature, weight loss and strain during the burnout--this sample will essentially be sacrificed but the amount of information gained will enable us to optimize the burnout cycle for this actuator size. MERCURY USAGE AND ALTERNATIVES IN THE ELECTRICAL AND ELECTRONICS INDUSTRIES Final Report

B. M. Sass, M. A. Salem, and L. A. Smith Jan. 1994 58 p See also

PB92-162569
(Contract EPA-68-C0-0003)
(PB94-165362; EPA/600/R-94/047) Avail: CASI HC A04/MF A01

Many industries have already found alternatives for mercury or have greatly decreased mercury use. However, the unique electromechanical and photoelectric properties of mercury and mercury compounds have made replacement of mercury difficult in some applications. The study was initiated to identify source reduction and recycling options for mercury in the electrical and electronics industry (SIC 36) and measurement and control instrument manufacture (SIC 382). The project identified trends in pollution prevention for mercury use throughout the U.S. economy by a review of the sources and use of mercury in the economy. Regulatory trends encouraging mercury pollution prevention were examined, and current practices in the electrical and electronics industry were reviewed in details to identify potential source reduction and reuse options for mercury. DESIGN AND PACKAGING ASPECTS OF MICROWAVE BANDWIDTH LITHIUM NIOBATE MODULATORS

C. F. McConaghy, S. Y. Lu, P. Sargis, M. Lowry, and R. A. Becker Jan. 1994 9 p Presented at the 4th Annual Advanced Research Project Agency (ARPA) Symposium on Photonics Systems for Antenna Applications, Monterey, CA, 18-21 Jan. 1994
(Contract W-7405-eng-48)
(DE94-016602; UCRL-JC-115676; CONF-940194-2) Avail: CASI HC A02/MF A01

Packaging of integrated optic modulators can be simplified if the electrodes are 50 ohms impedance. Recently built X-cut lithium niobate velocity matched modulators have a 50 ohm impedance. The interconnection of the modulators to external connectors by on-chip tapers is critical to their performance at frequencies in the 23 to 50 GHz frequency range. The attachment of fibers to the modulators is being enhanced with work on a robotic machine that uses a combination of machine vision and active alignment to both coarse and fine position the fiber to the waveguide. The design goal is to have each fiber attached in under 2 minutes. DOE

DSP CONTROL OF SUPERCONDUCTING QUANTUM INTERFERENCE DEVICES

R. R. Bracht, Pang-Jen Kung, P. S. Lewis, and E. R. Flynn 1994 7 p Presented at the ICSPAT 1994: Signal Procession Applications and Technology, Dallas, TX, 18-21 Oct. 1994
(Contract W-7405-eng-36)
(DE94-016193; LA-UR-94-2639; CONF-9410164-1) Avail: CASI HC A02/MF A01

Superconducting quantum interference devices (SQUIDS) are used to detect very low level magnetic fields. Los Alamos National Laboratory is involved in developing digital signal processing (DSP) based instrumentation for these devices in conjunction with detecting magnetic flux from the human brain. This field of application is known as magnetoencephalography (MEG). The magnetic signals generated by the brain are on the order of a billion times smaller than the earth's magnetic field, yet they can readily be detected with these highly sensitive magnetic detectors. Los Alamos National Laboratory has developed and implemented DSP control of the SQUID system. This has been accomplished by using an AT&T DSP32C DSP in conjunction with dual 18 bit a-to-d and d-to-a converters. The DSP performs the signal demodulation by synchronously sampling the recovered signal and applying the appropriate full wave rectification. The signal is then integrated and filtered and applied to the output. Also, the modulation signal is generated with the DSP system. All of the flux lock loop electronics are replaced except for the low noise analog preamplifier at the front of the recovery components. The system has been tested with both an electronic SQUID simulator and a low temperature thin film SQUID from Conductus. A number of experiments have been performed to allow evaluation of the system improvement made possible by use of DSP control. DOE

TRACKING A DYNAMIC SET OF FEATURE POINTS

Yi-Sheng Yao and Rama Chellappa Jun. 1994 36 p
(Contract DAAH04-93-G-0419; ARPA Order A422)
(AD-A285124; CAR-TR-720; CS-TR-3294) Avail: CASI HC A03/MF A01

This paper presents a model-based algorithm for tracking feature points over a long sequence of monocular noisy images with the ability to include new feature points detected in successive frames. The trajectory for each feature point is modeled by a simple kinematic motion model. A Probabilistic Data Association Filter is first designed to estimate the motion between two consecutive frames. A matching algorithm then identifies the corresponding point to subpixel accuracy and an Extended Kalman Filter (EKF) is employed to continually track the feature point. An efficient way to dynamically include new feature points from successive frames into a tracking list is also addressed. Tracking results for several image sequences are given. DTIC

TRIMODE POWER CONVERTER OPTIMIZES PV, DIESEL AND BATTERY ENERGY SOURCES

George OSullivan (Abacus Controls, Inc., Somerville, NJ.), Russell Bonn, and Ward Bower 1994 4 p Presented at the 1st World Conference on Photovoltaic Energy Conversion, Waikoloa, HI, 5-9 Dec. 1994
(Contract DE-AC04-94AL-85000)
(DE94-015014; SAND-94-1775C; CONF-941203-6) Avail: CASI HC A01/MF A01

Conservatively, there are 100,000 localities in the world waiting for the benefits that electricity can provide, and many of these are in climates where sunshine is plentiful. With these locations in mind a prototype 30 kW hybrid system has been assembled at Sandia to prove the reliability and economics of photovoltaic, diesel and battery energy sources managed by an autonomous power converter. In the Trimode Power Converter the same power parts, four IGBT's with an isolation transformer and filter components, serve as rectifier and charger to charge the battery from the diesel; as a stand-alone inverter to convert PV and battery energy to AC; and, as a parallel inverter with the diesel-generator to accommodate loads larger than the rating of the diesel. Whenever the diesel is supplying the load, an algorithm assures that the diesel is running at maximum efficiency by regulating the battery charger operating point. Given the profile of anticipated solar energy, the cost of transporting diesel fuel to a remote location and a five year projection of load demand, a method to size the PV array, battery and diesel for least cost is developed. DOE

LONG SEQUENCE CORRELATION COPROCESSOR Patent

Douglas W. Gage, inventor (to Navy) 20 Sep. 1994 8 p Filed 27 Jun. 1991
(AD-D016558; US-Patent-5,349,550; US-Patent-Appl-SN-772059; US-Patent-Class-364-728.03) Avail: US Patent and Trademark Office

A long sequence correlation coprocessor (LSCC) accelerates the bitwise correlation of arbitrarily long digital sequences by calculating in parallel the correlation score for 16, for example, adjacent bit alignments between two binary sequences. The LSCC integrated circuit is incorporated into a computer system with memory storage buffers and a separate general purpose computer processor which serves as its controller. Each of the LSCC's set of sequential counters simultaneously tallies a separate correlation coefficient. During each LSCC clock cycle, computer enable logic associated with each counter compares one bit of a first sequence with one bit of a second sequence to increment the counter if the bits are the same. A shift register assures that the same bit of the first sequence is simultaneously compared to different bits of the second sequence to simultaneously calculate the correlation coefficient by the different counters to represent different alignments of the two sequences. LOW ELECTRON BEAM ENERGY CIVA ANALYSIS OF PASSIVATED ICs

Edward I. Cole, Jr., Jerry M. Soden, Bruce A. Dodd, and Christopher L. Henderson 1994 11 p Presented at the International Symposium for Testing and Failure Analysis, Los Angeles, CA, 14-18 Nov. 1994
(Contract DE-AC04-94AL-85000)
(DE94-017421; SAND-94-1167C; CONF-941154-1) Avail: CASI HC A03/MF A01

Low Energy Charge-Induced Voltage Alteration (LECIVA) is a new scanning electron microscopy technique developed to localize open conductors in passivated IC's. LECIVA takes advantage of recent experimental work showing that the dielectric surface equilibrium voltage has an electron flux density dependence at low electron beam energies (less than or equal to 1.0 keV). The equilibrium voltage changes from positive to negative as the electron flux density is increased. Like Charge-Induced Voltage Alteration (CIVA), LECIVA images are produced from the voltage fluctuations of a constant current power supply as an electron beam is scanned over the IC surface. LECIVA image contrast is generated only by the electrically open part of a conductor, yielding, the same high selectivity demonstrated by CIVA. Because LECIVA is performed at low beam energies, radiation damage by the primary electrons and x-rays to MOS structures is far less than that caused by CIVA. LECIVA may also be performed on commercial electron beam test systems that do not have high primary electron beam energy capabilities. The physics of LECIVA signal generation are described. LECIVA imaging examples illustrate its utility on both a standard scanning electron microscope (SEM) and a commercial electron beam test system. DOE

PASOTRON(TM) TECHNOLOGY Final Report, 1 Jan. - 31 Dec. 1993

J. M. Butler, D. M. Goebel, and J. Santoru 1 Feb. 1994 33 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract F49620-92-C-0015)
(AD-A279994; HAC-REF-J4924; AFOSR-94-0311TR) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This annual report describes research progress made in the second year of the PASOTRON Technology Program. This program is a two year effort sponsored by the Air Force Office of Scientific Research to develop and investigate a single-stage amplifier and a multi-stage oscillator; each based on Hughes' Plasma-Assisted, Slow-Wave Oscillator (PASOTRON) technology. During the program's second year amplifier performance was briefly re-explored to take advantage of system and diagnostic upgrades implemented by HRL under a parallel IR&D Program; and the first stage of the multi-stage oscillator was demonstrated. Data is reported showing improved amplifier performance. Amplifier gains of 10-to-17 dB were maintained; while instantaneous bandwidth was increased from 0.1% to 1.0%. Amplified power levels of several tens to hundred kilowatts were measured to give a factor-of-ten increase in efficiency to levels of a few present. The first phase measurements were completed, and coherent amplifier operation was achieved with phase stability of up to 0.005 deg/V. Additionally, a multi-stage oscillator system was designed and experimental investigations were conducted on the first stage of the three-stage apparatus. Characterization of the second and third stages will be completed during the program's three-month no-cost extension. DTIC

PROTON IRRADIATION EFFECTS ON ADVANCED DIGITAL AND MICROWAVE III-V COMPONENTS

G. L. Hash, J. R. Schwank, M. R. Shaneyfelt, C. E. Sandoval, M. P. Connors, T. J. Sheridan, F. W. Sexton, E. M. Slayton, J. A. Heise, and C. Foster (Indiana Univ., Bloomington, IN.) 1994 8 p Presented at the 31st Annual International Nuclear and Space Radiation Effects Conference, Tucson, AZ, 18-22 Jul. 1994
(Contract DE-AC04-94AL-85000)
(DE94-018742; SAND-94-0205C; CONF-940726-14) Avail: CASI HC A02/MF A01

A wide range of advanced III-V components suitable for use in high-speed satellite communication systems were evaluated for displacement damage and single-event effects in high-energy, high-fluence proton environments. Transistors and integrated circuits (both digital and MMIC) were irradiated with protons at energies from 41 to 197 MeV and at fluences from 10(exp 10) to 2 x 10(exp 14) protons/sq cm. Large soft-error rates were measured for digital GaAs MESFET (3 x 10(exp -5) errors/bit-day) and heterojunction bipolar circuits (10(exp -5) errors/bit-day). No transient signals were detected from MMIC circuits. The largest degradation in transistor response caused by displacement damage was observed for 1.0-(mu)m depletion- and enhancement-mode MESFET transistors. Shorter gate length MESFET transistors and HEMT transistors exhibited less displacement-induced damage. These results show that memory-intensive GaAs digital circuits may result in significant system degradation due to single-event upset in natural and man-made space environments. However, displacement damage effects should not be a limiting factor for fluence levels up to 10(exp 14) protons/sq cm (equivalent to total doses in excess of 10 Mrad(GaAs)). DOE

BIOCONVERSION OF COAL DERIVED SYNTHESIS GAS TO LIQUID FUELS

M. K. Jain, R. M. Worden, and A. Grethlein 18 Jul. 1994 7 p
(Contract DE-AC22-92PC-92117)
(DE94-018849; DOE/PC-92117/T9) Avail: CASI HC A02/MF A01

The overall objective of the project is to develop an integrated two-stage fermentation process for conversion of coal-derived synthesis gas to a mixture of alcohols. This is achieved in two steps. In the first step, Butyribacterium methylotrophicum converts carbon monoxide (CO) to butyric and acetic acids. Subsequent fermentation of the acids by Clostridium acetobutylicum leads to the production of butanol and ethanol. The tasks for this quarter were: development/isolation of superior strains for fermentation of syngas; evaluation of bioreactor configuration for improved mass transfer of syngas; recovery of carbon and electrons from H2-CO2; initiation of pervaporation for recovery of solvents; and selection of solid support material for trickle-bed fermentation. Technical progress included the following: butyrate production was enhanced during H2/CO2 (50/50) batch fermentation; isolation of CO-utilizing anaerobic strains is in progress; pressure (15 psig) fermentation was evaluated as a means of increasing CO availability; polyurethane foam packing material was selected for trickle bed solid support; cell recycle fermentation on syngas operated for 3 months. Acetate was the primary product at pH 6.8; trickle bed and gas lift fermentor designs were modified after initial water testing; and pervaporation system was constructed (No alcohol selectivity was shown with the existing membranes during initial start-up). DOE

N95-20341# Sandia National Labs., Albuquerque, NM.

OBSERVATION OF EXCITONIC AND BAND-TO-BAND BEHAVIOR IN ORDERED InGaP2 ALLOYS

E. D. Jones, D. M. Follstaedt, H. Lee, J. S. Nelson, R. P. Schneider, Jr., R. G. Alonso (National Renewable Energy Lab., Golden, CO.), G. S. Horner (National Renewable Energy Lab., Golden, CO.), J. Machol (National Renewable Energy Lab., Golden, CO.), and A. Mascarenhas (National Renewable Energy Lab., Golden, CO.) 1994 5 p Presented at the 22nd International Conference on Physics of Semiconductors, Vancouver, British Columbia, 15-19 Aug. 1994
(Contract DE-AC04-94AL-85000)
(DE94-018891; SAND-94-2065C; CONF-9408155-4) Avail: CASI HC A01/MF A01

Photoluminescence measurements on ordered InGaP2 were studied as a function of temperature, laser power density, and magnetic field. The temperature varied between 1.4 and 300 K, the laser power densities ranged from 10 nW/sq cm to 20 W/sq cm, and the maximum magnetic field was 13.6 T. The data show both excitonic and band-to-band behavior, depending upon the incident laser power density. A consistent interpretation of all data leads to a type-II valence-band offset between the ordered domains. DOE

ANAEROBIC TREATMENT OF MUNICIPAL SOLID WASTE AND SLUDGE FOR ENERGY PRODUCTION AND RECYCLING OF NUTRIENTS
S. Leinonen, ed. 1993 113 p Workshop held in Joensuu, Finland, 1-2 Oct. 1993
(DE95-700217; JOY/KT-JULK-105; CONF-9310356) Avail: CASI HC A06/MF A02

This volume contains 18 papers presented at a Nordic workshop dealing with application of anaerobic decomposition processes on various types of organic wastes, held at the Siikasalmi Research and Experimental Station of the University of Joensuu on 1-2 Oct. 1992. Subject coverage of the presentations extends from the biochemical and microbiological principles of organic waste processing to descriptions and practical experiences of various types of treatment plants. The theoretical and experimental papers include studies on anaerobic and thermophilic degradation processes, methanogenesis, effects of hydrogen, treatment of chlorinated and phenolic compounds, and process modeling, while the practical examples range from treatment of various types of municipal, industrial, and mining wastes to agricultural and fish farm effluents. The papers provide technical descriptions of several biogas plants in operation. Geographically, the presentations span the Nordic and Baltic countries. DOE

BRUSHLESS DOUBLY-FED MACHINE SYSTEM DEVELOPMENT PROGRAM, PHASE 3 Final Technical Report, 1 Jan. 1992 - 30 Jun. 1993
G. C. Alexander, R. Spee, and A. K. Wallace 1993 171 p
(Contract DE-BI79-90BP-03362)
(DE94-013095; DOE/BP-03362/T1-Phase-3) Avail: CASI HC A08/MF A02

Since the inception of the Brushless Doubly-Fed Machine (BDFM) System Development Program in 1989, the value of BDFM technology has become apparent. The BDFM provides for adjustable speed, synchronous operation while keeping costs associated with the required power conversion equipment lower than in competing technologies. This provides for an advantage in initial as well as maintenance expenses over conventional drive system. Thus, the BDFM enables energy efficient, adjustable speed process control for applications where established drive technology has not been able to deliver satisfactory returns on investment. At the same time, the BDFM challenges conventional drive technologies in established markets by providing for improved performance at lower cost. BDFM converter rating is kept at a minimum, which significantly improves power quality at the utility interface over competing power conversion equipment. In summary, BDFM technology can be expected to provide significant benefits to utilities as well as their customers. This report discusses technical research and development activities related to Phase 3 of the BDFM System Development Program, including work made possible by supplemental funds for laboratory improvement and prototype construction. DOE

SOLID-STATE DYNAMICS AND QUANTUM TRANSPORT IN NOVEL SEMICONDUCTOR NANOSTRUCTURES Annual Report, 1 Oct. 1993 - 30 Sep. 1994
Sep. 1994 50 p
(Contract N00014-90-J-1835)
(AD-A285946) Avail: CASI HC A03/MF A01

The objective of this research program is to study theoretically the underlying principles of solid-state dynamics and quantum mechanical transport of carriers in ultrasmall novel semiconductor devices. The areas of research are: (1) theory of phonon modes in reduced dimensions; (2) effects of band structure on electronic and optical properties of heterostructures; and (3) quantum transport in solids with special emphasis on the non-perturbative role of high-electric fields and many-body effects in dynamical processes. The treatment of these problems is mainly analytical through the development of macroscopic and microscopic physical models with an emphasis on quantum mechanical principles. At the same time, numerical approaches has also been utilized for realistic solutions with accuracy. Specific subjects discussed in this report include the effects of confinement and localization on optical and acoustic phonon modes, band mixing in phonon-assisted transitions, and Bloch electron quantum transport theory under hot-electron conditions. The knowledge developed in this work will be of major importance in explaining the novel phenomena and fundamental questions relating to the breakdown of classical solid-state electronics as device dimensional scales are reduced to the submicron and ultra-submicron regime. DTIC

N95-20436 Department of the Navy, Washington, DC.
MODULE COOLING SYSTEM Patent
Frank E. Altoz, inventor (to Navy) 5 Jul. 1994 6 p Filed 25 Jun. 1993
(AD-D016584; US-Patent-5,325,913; US-Patent-Appl-SN-081712; US-Patent-Class-165-32) Avail: US Patent and Trademark Office

An apparatus is provided for cooling electronic components mounted on a circuit board. The circuit board is placed in thermal contact with a heat sink enclosure that has an interior cavity and a release opening that provides a path from the interior cavity to the external ambient. A meltable pellet blocks the release opening. A wick is bonded to the inside surface of the interior cavity. The device is sealed with a working fluid that permeates the wick. When the components get hot, the heat is transferred through the heat sink enclosure to the working fluid in the wick, causing the working fluid to vaporize. The vapors remain trapped in the interior cavity until the pellet melts, allowing the vapor to be released and the temperature of the heat sink enclosure to be stabilized or lowered. DTIC

THE RELIABILITY OF LASER REFLOWED Sn-Ag SOLDER JOINTS Quarterly Report No. 1
C. H. Raeder, D. L. Millard, and R. W. Messler 4 May 1994 5 p
(AD-A279787) Avail: CASI HC A01/MF A01

This is the first quarterly report of a project aimed at determining the reliability of electronic interconnects made with Sn-3.5wt%Ag solder alloy. The reliability of solder interconnects is primarily determined by two factors: (1) the type of electronic assembly; and (2) the environment to which the assembly is exposed. These two factors (each composed of several variables i.e. assembly thermal expansion coefficients, elastic moduli of assembly members, maximum operating temperature, rate of temperature change, etc.) boil down to three critical parameters; temperature, strain and strain rate (or stress). The interdependence of these variables must first be explored when addressing a creep-fatigue problem such as the case of solder joints. Specific environment (beyond temperature) and state of stress at a propagating crack, which are determined by the specific application and package geometry, are being neglected at this point in time. Little involving the creep or fatigue properties of Sn-3.5Ag is reported in the literature. Prior studies have used unique joint geometries to measure joint properties. DTIC

PROCEEDINGS OF THE 13TH SPACE PHOTOVOLTAIC RESEARCH AND TECHNOLOGY CONFERENCE (SPRAT 13)
Sep. 1994 421 p Conference held in Cleveland, OH, 14-16 Jun. 1994
(Contracts NAS1-19592; NAS3-26703; NAS3-27004; NAG3-1466; RTOP 233-01-0A)
(NASA-CP-3278; E-9083; NAS 1.55:3278) Avail: CASI HC A18/MF A04

The Thirteenth Space Photovoltaic Research and Technology (SPRAT) Conference included 38 technical papers, 6 program reviews and 5 workshop discussions. The effects of shrinking research and development budgets were evident in the focus and tone of this SPRAT. Most attendees appeared to be oriented toward near term, system oriented projects and fewer were involved in long term, high risk research. It was generally agreed that space power requirements would continue to move toward smaller (less than 2kW) power levels. Most future applications are believed to be in traditional orbits (LEO, GEO) although interesting opportunities may be found in high radiation, mid-altitude orbits useful for global communication networks. New solar cell devices and materials will be difficult to introduce unless they are mission enabling, or offer significant cost and/or performance benefits. Many factors influence the selection of type of array. For individual titles, see N95-20503 through N95-20543.

Avail: CASI HC A03/MF A04

The Goddard Space Flight Center (GSFC) develops and operates a wide variety of spacecraft for conducting NASA's communications, space science, and earth science missions. Some are 'in house' spacecraft for which the GSFC builds the spacecraft and performs all solar array design, analysis, integration, and test. Others are 'out of house' spacecraft for which an aerospace contractor builds the spacecraft and develops the solar array under direction from GSFC. The experience of developing flight solar arrays for numerous GSFC 'in house' and 'out of house' spacecraft has resulted in an understanding of solar array requirements for many different applications. This presentation will review those solar array requirements that are common to most GSFC spacecraft. Solar array technologies will be discussed that are currently under development and that could be useful to future GSFC spacecraft. Author

Funding for the terrestrial photovoltaic's program is $78 million in 1994. This is more than double the minimum level reached in 1989 and runs counter to the general trend of decreasing budgets for Department of Energy (DOE) programs. During the past five years, the program has expanded its mission from research and development to also address manufacturing technology and commercialization assistance. These new activities are directed toward revitalizing the market to reinstate the rapid rate of sales growth needed to attract investment. The program is approaching balance among efforts in each of the three areas. This translates to a reduction in some of the R & D activities of most relevance to the space power community. On the other hand, some of the advancements in manufacturing may finally bring thin-film technologies to reality for space arrays. This talk will describe the status and direction of DOE program with an eye toward highlighting its impact on technology of interest for space. Author

The current space PV (photovoltaic) technology development program of ESA is described. The program is closely coupled to the European space mission scenario for the next 10 year period and has as its main objective to make the most effective use of the limited resources available for technology in the present economical climate. This requires a well-balanced approach between concentration on very few options and keeping the competition alive if more than one promising technology exists. The paper describes ESA's main activities in the areas of solar array technology, solar cell technology, solar cell assembly technology, and special test and verification activities including the in-orbit demonstration of new technologies. Avail: CASI HC A02/MF A04

We report on the development and performance of deep-junction (approximately 0.25 micron), graded-emitter-doped, n(sup +)-p InP solar cells grown by metallorganic chemical vapor deposition (MOCVD). A novel, diffusion-transport process for obtaining lightly-doped p-type base regions of the solar cell is described. The I-V data and external quantum-efficiency response of these cells are presented. The best active-area AMO efficiency for these deep-junction cells on (100)-oriented InP substrates is 16.8 percent, with a J(sub SC) of 31.8 mA/sq cm, a V(sub OC) of 0.843 V, and a fill-factor of 0.85. By comparison, the best cell efficiency on the (111)B-oriented InP substrates was 15.0 percent. These efficiency values for deep-junction cells are encouraging and compare favorably with performance of thin-emitter (0.03 micron) epitaxial cells as well as that of deep-emitter diffused cells. The cell performance and breakdown voltage characteristics of a batch of 20 cells on each of the orientations are presented, indicating the superior breakdown voltage properties and other characteristics of InP cells on the (111)B orientation. Spectral response, dark I-V data, and photoluminescence (PL) measurements on the InP cells are presented with an analysis on the variation in J(sub SC) and V(sub OC) of the cells. It is observed, under open-circuit conditions, that lower-V(sub OC) cells exhibit higher band-edge PL intensity for both the (100) and (111)B orientations. This anomalous behavior suggests that radiative recombination in the heavily-doped n(sup +)-InP emitter may be detrimental to achieving higher V(sub OC) in n(sup +)-p InP solar cells. Author

InP-based multijunction tandem solar cells show great promise for the conversion efficiency (eta) and high radiation resistance. InP and its related ternary and quanternary compound semiconductors such as InGaAs and InGaAsP offer desirable combinations for energy bandgap values which are very suitable for multijunction tandem solar cell applications. The monolithically integrated InP/In(0.53)Ga(0.47)As tandem solar cells are expected to reach efficiencies above 30 percent. Wanlass, et.al., have reported AMO efficiencies as high as 20.1% for two terminal cells fabricated using atmospheric-pressure metalorganic vapor phase epitaxy (APMOVPE). The main limitations in their technique are first related to the degradation of the intercell ohmic contact (IOC), in this case the In(0.53)Ga(0.47)As tunnel junction during the growth of the top InP subcell structure, and second to the current matching, often limited by the In(0.53)Ga(0.47)As bottom subcell. Chemical beam epitaxy (CBE) has been shown to allow the growth of high quality materials with reproducible complex compositional and doping profiles. The main advantage of CBE compared to metalorganic chemical vapor deposition (MOCVD), the most popular technique for InP-based photovoltaic device fabrication, is the ability to grow high purity epilayers at much lower temperatures (450 C - 530 C). In a recent report it was shown that cost-wise CBE is a breakthrough technology for photovoltaic (PV) solar energy progress in the energy conversion efficiency of InP-based solar cells fabricated using chemical beam epitaxy. This communication summarizes our recent results on PV devices and demonstrates the strength of this new technology. Author (revised)

Recently, we have succeeded in fabricating diffused junction p(sup +)n(Cd,S) InP solar cells with measured AMO, 25 C open circuit voltage (V(sub OC)) of 887.6 mV, which, to the best of our knowledge, is higher than previously reported V(sub OC) values for any InP homojunction solar cells. The experiment-based projected achievable efficiency of these cells using LEC grown substrates is 21.3 percent. The maximum AMO, 25 C internal losses due to date on bare cells is, however, only 13.2 percent. This is because of large external and internal losses due to non-optimized front grid design, antireflection (AR) coating and emitter thickness. This paper summarizes recent advances in the technology of fabrication of p(sup +)n InP diffused structures and solar cells, resulted from a study undertaken in an effort to increase the cell efficiency. The topics discussed in this paper include advances in: (1) the formation on thin p(sup +) InP:Cd emitter layers, (2) electroplated front contacts, (3) surface passivation and (4) the design of a new native oxide/Al2O3/MgF2 tree layer AR coating using a chemically-grown P-rich passivating oxide as a first layer. Based on the high radiation resistance and the excellent post-irradiation annealing and recovery demonstrated in the early tests done to date, as well as the projected high efficiency and low-cost high-volume fabricability, these cells show a very good potential for space photovoltaic applications.

InP on Si solar cells combine the low-cost and high-strength of Si with the high efficiency and radiation tolerance of InP. The main obstacle in the growth of single crystal InP-on-Si is the high residual strain and high dislocation density of the heteroepitaxial InP films. The dislocations result from the large differences in lattice constant and thermal expansion mismatch of InP and Si. Adjusting the size and geometry of the growth area is one possible method of addressing this problem. In this work, we conducted a material quality study of liquid phase epitaxy overgrowth layers on selective area InP grown by a proprietary vapor phase epitaxy technique on Si. The relationship between growth area and dislocation density was quantified using etch pit density measurements. Material quality of the InP on Si improved both with reduced growth area and increased aspect ratio (length/width) of the selective area. Areas with etch pit density as low as 1.6 x 10(exp 4) sq cm were obtained. Assuming dislocation density is an order of magnitude greater than etch pit density, solar cells made with this material could achieve the maximum theoretical efficiency of 23% at AMO. Etch pit density dependence on the orientation of the selective areas on the substrate was also studied. Author

Indium phosphide (InP) P-on-N one-sun solar cells were epitaxially grown using a metalorganic chemical vapor deposition process on germanium (Ge) wafers. The motivation for this work is to replace expensive InP wafers, which are fragile and must be thick and therefore heavy, with less expensive Ge wafers, which are stronger, allowing use of thinner, lighter weight wafers. An intermediate InxGs1-xP grading layer starting as In(0.49)Ga(0.51) at the GaAs-coated Ge wafer surface and ending as InP at the top of the grading layer (backside of the InP cell) was used to attempt to bend some of the threading dislocations generated by lattice-mismatch between the Ge wafer and InP cell so they would be harmlessly confined in this grading layer. The best InP/Ge cell was independently measured by NASA-Lewis with a one-sun 25 C AMO efficiently measured by NASA-Lewis with a one-circuit photocurrent 22.6 mA/sq cm. We believe this is the first published report of an InP cell grown on a Ge wafer. Why get excited over a 9 percent InP/Ge cell? If we look at the cell weight and efficiency, a 9 percent InP cell on an 8 mil Ge wafer has about the same cell power density, 118 W/kg (BOL), as the best InP cell ever made, a 19 percent InP cell on an 18 mil InP wafer, because of the lighter Ge wafer weight. As cell panel materials become lighter, the cell weight becomes more important, and the advantage of lightweight cells to the panel power density becomes more important. In addition, although InP/Ge cells have a low beginning-of-life (BOL) efficiency due to dislocation defects, the InP/Ge cells are very radiation hard (end-of-life power similar to beginning-of-life). We have irradiated an InP/Ge cell with alpha particles to an equivalent fluence of 1.6 x 10(exp 16) 1 MeV electrons/sq cm and the efficiency is still 83 percent of its BOL value. At this fluence level, the power output of these InP/Ge cells matches the GaAs/Ge cell data tabulated in the JPL handbook. Data are presented indicating InP/Ge has more power output than GaAs/Ge cells at fluences in excess of this value.

Polycrystalline thin film solar cells fabricated on light-weight, flexible substrates are very attractive for space applications. In this work CuInSe2 (CIS) based thin film devices were processed on metallic foil substrates using the selenization technique. CIS deposition method involved reaction of electron-bean evaporated Cu-In precursor layers with a selenizing atmosphere at around 400 C. Several metallic foils such as Mo, Ti, Al, Ni, and Cu were evaluated as possible substrates for these devices. Solar cells with AM1.5 efficiencies of 9.0-9.34 percent and good mechanical integrity were demonstrated on Mo and Ti foils. Monolithic integration of these devices was also demonstrated up to 4 in x 4 in size. Author

This paper describes ultra-lightweight, high performance, thin, light trapping GaAs solar cells for advanced space power systems. The device designs can achieve 24.5 percent efficiency at AMO and 1X conditions, corresponding to a power density of 330 W/m2. A significant breakthrough lies in the potential for a specific power of 2906 W/kg because the entire device is less than 1.5 microns thick. This represents a 440 percent improvement over conventional 4-mil silicon solar cells. In addition to being lightweight, this thin device design can result in increased radiation tolerance. The attachment of the cover glass support to the front surface has been demonstrated by both silicone and electrostatic bonding techniques. Device parameters of 1.002 volts open-circuit voltage, 80 percent fill factor, and a short-circuit current of 24.3 mA/sq cm have been obtained. This demonstrates a conversion efficiency of 14.4 percent resulting in a specific power of 2240 W/kg. Additionally, this new technology offers an alternative approach for enabling multi-bandgap solar cells and high output space solar power devices. The thin device structure can be applied to any 3-5 based solar cell application, yielding both an increase in specific power and radiation tolerance. Author

Polycrystalline, thin-film photovoltaics represent one of the few (if not the only) renewable power sources which has the potential to satisfy the demanding technical requirements for future space applications. The demand in space is for deployable, flexible arrays with high power-to-weight ratios and long-term stability (15-20 years). In addition, there is also the demand that these arrays be produced by scalable, low-cost, high yield, processes. An approach to significantly reduce costs and increase reliability is to interconnect individual cells series via monolithic integration. Both CIS and CdTe semiconductor films are optimum absorber materials for thin-film n-p heterojunction solar cells, having band gaps between 0.9-1.5 ev and demonstrated small area efficiencies, with cadmium sulfide window layers, above 16.5 percent. Both CIS and CdTe polycrystalline thin-film cells have been produced on a laboratory scale by a variety of physical and chemical deposition methods, including evaporation, sputtering, and electrodeposition. Translating laboratory processes which yield these high efficiency, small area cells into the design of a manufacturing process capable of producing 1-sq ft modules, however, requires a quantitative understanding of each individual step in the process and its (each step) effect on overall module performance. With a proper quantification and understanding of material transport and reactivity for each individual step, manufacturing process can be designed that is not 'reactor-specific' and can be controlled intelligently with the design parameters of the process. The objective of this paper is to present an overview of the current efforts at MMC to develop large-scale manufacturing processes for both CIS and CdTe thin-film polycrystalline modules. CIS cells/modules are fabricated in a 'substrate configuration' by physical vapor deposition techniques and CdTe cells/modules are fabricated in a 'superstrate configuration' by wet chemical methods. Both laser and mechanical scribing operations are used to monolithically integrate (series interconnect) the individual cells into modules. Results will be presented at the cell and module development levels with a brief description of the test methods used to qualify these devices for space applications. The approach and development efforts are directed towards large-scale manufacturability of established thin-film, polycrystalline processing methods for large area modules with less emphasis on maximizing small area efficiencies. Progress is reported with respect to the development of thin film amorphous (alpha-Si) terrestrial solar cells for space applications. Such devices promise to result in very lightweight, low cost, flexible arrays with superior end of life (EOL) performance. Each alpha-Si cell consists of a tandem arrangement of three very thin p-i-n junctions vapor deposited between film electrodes. The thickness of this entire stack is approximately 2.0 microns, resulting in a device of negligible weight, but one that must be mechanically supported for handling and fabrication into arrays. The stack is therefore presently deposited onto a large area (12 by 13 in), rigid, glass superstrate, 40 mil thick, and preliminary space qualification testing of modules so configured is underway. At the same time, a more advanced version is under development in which the thin film stack is transferred from the glass onto a thin (2.0 mil) polymer substrate to create large arrays that are truly flexible and significantly lighter than either the glassed alpha-Si version or present conventional crystalline technologies. In this paper the key processes for such effective transfer are described. In addition, both glassed (rigid) and unglassed (flexible) alpha-Si cells are studied when integrated with various advanced structures to form lightweight systems. EOL predictions are generated for the case of a 1000 W array in a standard, 10 year geosynchronous (GEO) orbit. Specific powers (W/kg), power densities (W/sq m) and total array costs ($/sq ft) are compared. Author

Solar cells have been used to convert sunlight to electrical energy for many years and also offer great potential for non-solar energy conversion applications. Their greatly improved performance under monochromatic light compared to sunlight, makes them suitable as photovoltaic (PV) receivers in laser power beaming applications. Laser beamed power to a PV array receiver could provide power to satellites, an orbital transfer vehicle, or a lunar base. Gallium arsenide (GaAs) and indium phosphide (InP) solar cells have calculated efficiencies of more than 50 percent under continuous illumination at the optimum wavelength. Currently high power free-electron lasers are being developed which operate in pulsed conditions. Understanding cell behavior under a laser pulse is important in the selection of the solar cell material and the laser. An experiment by NAsA lewis and JPL at the AVLIS laser facility in Livermore, CA presented experimental data on cell performance under pulsed laser illumination. Reference 5 contains an overview of technical issues concerning the use of solar cells for laser power conversion, written before the experiments were performed. As the experimental results showed, the actual effects of pulsed operation are more complicated. Reference 6 discusses simulations of the output of GaAs concentrator solar cells under pulsed laser illumination. The present paper continues this work, and compares the output of Si and GaAs solar cells. Author

Research and Technology Conference (SPRAT 13) Sep. 1994 p 141-146 (For primary document see N95-20502 06-33)
Avail: CASI HC A02/MF A04

An analysis of InP/GaAs tandem solar cell structure has been undertaken to allow for maximum AMO conversion efficiencies (space applications) while still taking into account both the theoretical and technological limitations. The dependence of intrinsic and extrinsic parameters such as diffusion lengths and generation-recombination (GR) lifetimes on N/P and P/N devices performances are clearly demonstrated. We also report for the first time the improvement attainable through the use of a new patterned tunnel junction as the inter cell ohmic interconnect. Such a design minimizes the light absorption in the interconnect region and leads to a noticeable increase in the cell efficiency. Our computations predict 27 percent AMO efficiency for N/P tandems with ideality factor gamma = 2 (GR lifetimes approximately equal 1 micron), and 36 percent for gamma = 1 (GR lifetimes approximately equals 100 microns). The method of optimization and the values of the physical and optical parameters are discussed.

PERFORMANCE, DEFECT BEHAVIOR AND CARRIER ENHANCEMENT IN LOW ENERGY, PROTON IRRADIATED p+nn+ InP SOLAR CELLS **c44**

I. Weinberg, G. C. Rybicki, C. Vargas-Aburto (Kent State Univ., OH.), R. K. Jain (Toledo Univ., OH.), and D. Scheiman (NYMA, Inc., Brook Park, OH.) *In its* Proceedings of the 13th Space Photovoltaic Research and Technology Conference (SPRAT 13) Sep. 1994 p 149-158 (For primary document see N95-20502 06-33)
Avail: CASI HC A02/MF A04

The highest AMO efficiency (19.1 percent) InP solar cell consisted of an n+pp+ structure epitaxially grown on a p+ InP substrate. However, the high cost and relative fragility of InP served as motivation for research efforts directed at heteroepitaxial growth of InP on more viable substrates. The highest AMO efficiency (13.7 percent) for this type of cell was achieved using a GaAs substrate. Considering only cost and fracture toughness, Si would be the preferred substrate. The fact that Si is a donor in InP introduces complexities which are necessary in order to avoid the formation of an efficiency limiting counterdiode. One method used to overcome this problem lies in employing an n+p+ tunnel junction in contact with the cell's p region. A simpler method consists of using an n+ substrate and processing the cell in the p+ nn+ configuration. This eliminates the need for a tunnel junction. Unfortunately, the p/n configuration has received relatively little attention the best cell with this geometry having achieved an efficiency of 17 percent. Irradiation of these homoepitaxial cells, with 1 Mev electrons, showed that they were slightly more radiation resistant than diffused junction n/p cells. Additional p/n InP cells have been processed by some activity aimed at diffusion. Currently, there has been some activity aimed at producing heteroepitaxial p+nn+ InP cells using n+ Ge substrates. Since, like Si, Ge is an n-dopant in InP, use of this configuration obviates the need for a tunnel junction. Obviously, before attempting to process heteroepitaxial cells, one must produce a reasonably good homoepitaxial cell. In the present case we focus our attention on homoepitaxially on an n+ Ge substrate.

ELECTRON-IRRADIATED TWO-TERMINAL, MONOLITHIC InP/Ga0.47In0.53As TANDEM SOLAR CELLS AND ANNEALING OF RADIATION DAMAGE **c44**

H. L. Cotal, Robert J. Walters, Geoffrey P. Summers, and Scott R. Messenger (SFA, Inc., Landover, MD.) *In* NASA. Lewis Research Center, Proceedings of the 13th Space Photovoltaic Research and Technology Conference (SPRAT 13) Sep. 1994 p 159-166 (For primary document see N95-20502 06-33)
Avail: CASI HC A02/MF A04

Radiation damage results from two-terminal monolithic InP/Ga(0.47)In(0.53)As tandem solar cells subject to 1 MeV electron irradiation are presented. Efficiencies greater than 22 percent have been measured by the National Renewable Energy Laboratory from 2x2 sq cm cells at 1 sun, AMO (25 C). The short circuit current density, open circuit voltage and fill factor are found to tolerate the same amount of radiation at low fluences. At high fluence levels, slight differences are observed. Decreasing the base amount of radiation at the Ga(0.47)In(0.53)As bottomcell improved the radiation resistance of J(sub sc) dramatically. This is turn, extended the series current flow through the subcell substantially up to a fluence of 3x10(exp 15) cm(exp -2) compared to 3x10(exp 14) cm(exp -2), as observed previously. The degradation of the maximum power output form tandem device is comparable to that from shallow homojunction (SHJ) InP solar cells, and the mechanism responsible for such degradation is explained in terms of the radiation response of the component cells. Annealing studies revealed that the recovery of the tandem cell response is dictated by the annealing characteristics exhibited by SHJ InP solar cells.

RADIATION EFFECTS ON p+n InP JUNCTIONS GROWN BY MOCVD **c44**

Scott R. Messenger, Robert J. Walters (Naval Research Lab., Washington, DC.), M. J. Panunto (Maryland Univ., Baltimore, MD.), and Geoffrey P. Summers (Naval Research Lab., Washington, DC.) *In* NASA. Lewis Research Center, Proceedings of the 13th Space Photovoltaic Research and Technology Conference (SPRAT 13) Sep. 1994 p 167-180 (For primary document see N95-20502 06-33)
Avail: CASI HC A03/MF A04

The superior radiation resistance of InP over other solar cell materials such as Si or GaAs has prompted the development of InP cells for space applications. The early research on radiation effects in InP was performed by Yamaguchi and co-workers who showed that, in diffused p-InP junctions, radiation-induced defects were readily annealed both thermally and by injection, which was accompanied by significant cell recovery. More recent research efforts have been made using p-InP grown by metalorganic chemical vapor deposition (MOCVD). While similar deep level transient spectroscopy (DLTS) results were found for radiation induced defects in these cells and in diffused junctions, significant differences existed in the annealing characteristics. After injection annealing at room temperature, Yamaguchi noticed an almost complete recovery of the photovoltaic parameters, while the MOCVD samples showed only minimal annealing. In searching for an explanation of the different annealing behavior of diffused junctions and those grown by MOCVD, several possibilities have been considered. One possibility is the difference in the emitter structure. The diffused junctions have S-doped graded emitters with widths of approximately 0.3 micrometers, while the MOCVD emitters are often doped with Si and have widths of approximately 300A (0.03 micrometers). The difference in the emitter thickness can have important effects, e.g. a larger fraction of the total photocurrent is generated in the n-type material for thicker emitters. Therefore the properties of the n-InP material may explain the difference in the observed overall annealing behavior of the cells.

In recently years, Ga(0.5)In((0.5)P/GaAs cells have drawn increased attention both because of their high efficiencies and because they are well suited for space applications. They can be grown and processed as two-junction devices with roughly twice the voltage and half the current of GaAs cells. They have low temperature coefficients, and have good potential for radiation hardness. We have previously reported the effects of electron irradiation on test cells which were not optimally designed for space. From those results we estimated that an optimally designed cell could achieve 20 percent after irradiation with 10(exp 15) cm(exp -2) 1 MeV electrons. Modeling studies predicted that slightly higher efficiencies may be achievable. Record efficiencies for EOL performance of other types of cells are significantly lower. Even the best Si and InP cells have BOL efficiencies lower than the EOL efficiency we report here. Good GaAs cells have an EOL efficiency of 16 percent. The InP/Ga(0.5)In(0.5)As two-junction, two-terminal device has a BOL efficiency as high as 22.2 percent, but radiation results for these cells were limited. In this study we use the previous modeling and irradiation results to design a set of

Ga(0.5)In(0.5)P/GaAs cells that will demonstrate the importance of the design parameters and result in high-efficiency devices. We report record AMO efficiencies: a BOL efficiency of 25.7 percent for a device optimized for BOL performance and two of different designs with EOL efficiencies of 19.6 percent (at 10(exp 15) cm(exp -2) 1MeV electrons). We vary the bottom-cell base doping and the top-cell thickness to show the effects of these two important design parameters. We get an unexpected result indicating that the dopant added to the bottom-cell base also increases the degradation of the top cell. Author

INVESTIGATION OF THE STABILITY AND 1.0 MeV PROTON RADIATION RESISTANCE OF COMMERCIALLY PRODUCED HYDROGENATED AMORPHOUS SILICON ALLOY SOLAR CELLS c44
Kenneth R. Lord, II, Michael R. Walters, and James R. Woodyard *In* NASA. Lewis Research Center, Proceedings of the 13th Space Photovoltaic Research and Technology Conference (SPRAT 13) Sep. 1994 p 187-196 Sponsored in cooperation with NASA, TRW and Wayne State Univ. Inst. for Mfg. Research (For primary document see N95-20502 06-33)
Avail: CASI HC A02/MF A04

The radiation resistance of commercial solar cells fabricated from hydrogenated amorphous silicon alloys is reported. A number of different device structures were irradiated with 1.0 MeV protons. The cells were annealing at 200 C. The annealing time was dependent on proton fluence. Annealing devices for one hour restores cell parameters or fluences below 1(exp 14) cm(exp -2); fluences above 1(exp 14) cm(exp -2) require longer annealing times. A parametric fitting model was used to characterize current mechanisms observed in dark I-V measurements. The current mechanisms were explored with irradiation fluence, and voltage and light soaking times. The thermal generation current density and quality factor increased with proton fluence. Device simulation shows the degradation in cell characteristics may be explained by the reduction of the electric field in the intrinsic layer. Author

THE USE OF DISPLACEMENT DAMAGE DOSE TO CORRELATE DEGRADATION IN SOLAR CELLS EXPOSED TO DIFFERENT RADIATIONS c44
Geoffrey P. Summers, Edward A. Burke (SFA, Inc., Landover, MD.), Philip Shapiro (SFA, Inc., Landover, MD.), Richard Statler (SFA, Inc., Landover, MD.), Scott R. Messenger (SFA, Inc., Landover, MD.), and Robert J. Walters *In* NASA. Lewis Research Center, Proceedings of the 13th Space Photovoltaic Research and Technology Conference (SPRAT 13) Sep. 1994 p 197-201 (For primary document see N95-20502 06-33)
Avail: CASI HC A01/MF A04

It has been found useful in the past to use the concept of 'equivalent fluence' to compare the radiation response of different solar cell technologies. Results are usually given in terms of an equivalent 1 MeV electron or an equivalent 10 MeV proton fluence. To specify cell response in a complex space-radiation environment in terms of an equivalent fluence, it is necessary to measure damage coefficients for a number of representative electron and proton energies. However, at the last Photovoltaic Specialist Conference we showed that nonionizing energy loss (NIEL) could be used to correlate damage coefficients for protons, using measurements for GaAs as an example. This correlation means that damage coefficients for all proton energies except near threshold can be predicted from a measurement made at one particular energy. NIEL is the exact equivalent for displacement damage of linear energy transfer (LET) for ionization energy loss. The use of NIEL in this way leads naturally to the concept of 10 MeV equivalent proton fluence. The situation for electron damage is more complex, however. It is shown that the concept of 'displacement damage dose' gives a more general way of unifying damage coefficients. It follows that 1 MeV electron equivalent fluence is a special case of a more general quantity for unifying electron damage coefficients which we call the 'effective 1 MeV electron equivalent dose'. ANNEALING OF IRRADIATED n+p InP BURIED HOMOJUNCTIONS c44
Robert J. Walters, Geoffrey P. Summers, M. L. Timmons (Research Triangle Inst., Research Triangle Park, NC.), R. Venkatasubramanian (Research Triangle Inst., Research Triangle Park, NC.), J. A. Hancock (Research Triangle Inst., Research Triangle Park, NC.), and J. S. Hills (Research Triangle Inst., Research Triangle Park, NC.) *In* NASA. Lewis Research Center, Proceedings of the 13th Space Photovoltaic Research and Technology Conference (SPRAT 13) Sep. 1994 p 203-212 (For primary document see N95-20502 06-33)
Avail: CASI HC A02/MF A04

At the last SPRAT conference, the Naval Research Laboratory (NRL) presented results from two experiments. One studied n+p diffused junction (DJ) InP solar cells, and the other studied n+p shallow homojunction (SHJ) InP mesa diodes grown by metalorganic chemical vapor deposition (MOCVD). The former work showed that a DJ solar cell in which the maximum power P(sub max) had been degraded by nearly 80 percent under irradiation recovered completely under short circuit illumination at 450K. The recovery was accompanied by the removal of all but one of the radiation-induced defect levels. The latter work, on the other hand, showed that the radiation-induced defects in the SHJ diodes did not anneal until the temperature reached 650K. These results suggest that an irradiated DJ solar cell, under illumination, will anneal at a temperature 200K lower than an irradiated SHJ cell. This is an unexpected result considering the similarity of the devices. The goal of the present research is to explain this different behavior. This paper investigates two points which arose from the previous studies. The first point is that the DJ cells were annealed under illumination while the SHJ diodes were annealed without bias. The second point investigated here is that the emitters of the DJ and SHJ devices were significantly different. Author

QUALIFICATION TEST RESULTS FOR BLUE-RED REFLECTING SOLAR COVERS c44
W. T. Beauchamp *In* NASA. Lewis Research Center, Proceedings of the 13th Space Photovoltaic Research and Technology Conference (SPRAT 13) Sep. 1994 p 213-222 Presented at the Proceedings of the 23d IEEE Photospecialist Conference, Louisville, KY, May 1994 (For primary document see N95-20502 06-33)
Avail: CASI HC A02/MF A04

Recent market forces and design innovations have spurred the development of solar cell covers that significantly reduce the solar absorptance for a cell array. GaAs cells, using Ge as the substrate host material, can have a significantly higher output if the solar absorptance of the cell array is reduced. New optical coating design techniques have allowed the construction of covers that reflect the ultraviolet energy (below 350 nm) and the near infrared energy (above 900 nm) resulting in the beneficial reduction in absorptance. Recent modeling suggests three or more present output increase due to the lowered temperature with such a device. Within the last several months we have completed the testing of production samples of these new covers in a qualification series that included the usual environmental effects associated with the routine testing of solar cell covers and the combined effects of protons, electrons and solar UV as would be encountered in space. For the combined effects testing the samples were exposed to 300 sun days equivalent UV, 5 x 10(exp 14)/sq cm of 0.5 MeV protons and 10(exp 15)/sq cm of 1.0 MeV electrons. Measurements of the reflectance, transmission, emittance and other appropriate parameters were made before and after the testing. As measured by the averaged transmission over the cell operating band, the change in transmission for the samples was less than or about equal to 1 percent. The details of the testing and the results in terms of transmission, reflectance and emittance are discussed in the paper. Author

UV TESTING OF INTELSAT-7, 7A, AND 8 SOLAR CELLS c44
A. Meulenberg *In* NASA. Lewis Research Center, Proceedings of the 13th Space Photovoltaic Research and Technology Conference (SPRAT 13) Sep. 1994 p 223-225 (For primary document see N95-20502 06-33)
Avail: CASI HC A01/MF A04

A 4000 hour experiment, conducted in late 1992 through mid 1993, confirmed earlier results on the ultraviolet damage effects in covered solar cells of various types being used, or proposed for use, in INTELSAT programs. Two different UV test systems were used to identify systematic errors and to study the effects of UV source-bulb age on degradation rate. After correction for contamination and UV source-bulb aging, the extrapolated degradation rates for irradiated and unirradiated INTELSAT-5, -6 single AR(SAR) coated cells and INTELSAT-7, -7A, -8 double layer AR(DAR) coated cells in both the 1993 tests confirm the following hypotheses resulting from the 1992 experiment. (a) Irradiated cells display significantly more UV degradation than do the unirradiated cells for tests exceeding 2000 hours. The new data indicates that degradation effects from electron irradiation are proportional to t(exp 2) (the square of the UV hours), at least for times less than or equal to 3000 hours. (b) This difference does not depend upon entire reflective coating, cell resistivity, or manufacturer within the sensitivity and reproducibility of the experiment. (c) There is a clear difference in degradation rate between single AR coated cells (TiO(x)) and double layer AR coated cells (SiO(x) and Al2O3?). At 100,000 hours (11.4 years) the DAR coated cells display more degradation than do the SAR coated cells, even though at 1,000 hours the DAR cells display less degradation. (d) UV degradation rates, to modern covered silicon solar cells, at the beginning of bulb life drop from approximately 2 times the average rate to near zero after 2000 hours (average end-of-life for the xenon short-arc lamps used in the tests). The effects of 1 MeV electron irradiation (10(exp 15) e(-)/sq cm) prior to UV exposure are clearly indicated in the plot of percent change in cell open circuit voltage (Voc) versus percent change in short circuit current (Isc) during the UV test and post-test cleanup of the cells. Clearly, extended UV testing produces a permanent photo-induced redegradation of previously irradiated cells. However, this photo-induced redegradation may be caused by the long-wavelength light, not the UV light. Author

PARASITIC CURRENT COLLECTION BY SOLAR ARRAYS IN LEO c44
Victoria A. Davis and Barbara M. Gardner *In* NASA. Lewis Research Center, Proceedings of the 13th Space Photovoltaic Research and Technology Conference (SPRAT 13) Sep. 1994 p 227-235 Sponsored by AF Materiel Command (For primary document see N95-20502 06-33)
Avail: CASI HC A02/MF A04

Solar cells at potentials positive with respect to a surrounding plasma collect electrons. Current is collected by the exposed high voltage surfaces: the interconnects and the sides of the solar cells. This current is a drain on the array power that can be significant for high-voltage arrays. In addition, this current influences the current balance that determines the floating potential of the spacecraft. One of the objectives of the Air Force (PL/GPS) PASP Plus experiment is an improved understanding of parasitic current collection. As part of the PASP Plus program, we are using computer modeling to improve our understanding of the physical processes that control parasitic current collection. Author

The Advanced Photovoltaic Experiment (APEX) was designed to generate laboratory reference standards as well as to explore the durability of a wide variety of space solar cells. In addition to the cells, it was equipped with an absolute cavity radiometer to measure solar intensity, a spectroradiometer to measure the spectral content of this radiation, and a sun angle sensor. Data from the solar cells and various sensors was obtained on a daily basis during the first eleven months of the 69 month flight. We compare pre-flight and post-flight laboratory measurements with on-orbit calibration data. Pre-flight and post-flight calibration data for the cavity radiometers as well as on-orbit data demonstrated the accuracy and durability of the Eppley Labs instrument flown on APEX. Author

PRELIMINARY RESULTS FROM THE FLIGHT OF THE SOLAR ARRAY MODULE PLASMA INTERACTIONS EXPERIMENT (SAMPIE) c44
Dale C. Ferguson and G. Barry Hillard *In its* Proceedings of the 13th Space Photovoltaic Research and Technology Conference (SPRAT 13) Sep. 1994 p 247-256 (For primary document see N95-20502 06-33)
Avail: CASI HC A02/MF A04

SAMPIE, the Solar Array Module Plasma Interactions Experiment, flew in the Space Shuttle Columbia payload bay as part of the Office of Aeronautics and Space Technology-2 (OAST-2) mission on STS-62, March, 1994. SAMPIE biased samples of solar arrays and space power materials to varying potentials with respect to the surrounding space plasma, and recorded the plasma currents collected and the arcs which occurred, along with a set of plasma diagnostics data. A large set of high quality data was obtained on the behavior of solar arrays and space power materials in the space environment. This paper is the first report on the data SAMPIE telemetered to the ground during the mission. It will be seen that the flight data promise to help determine arcing thresholds, snapover potentials, and floating potentials for arrays and spacecraft in LEO. Author (revised)

PHOTOVOLTAIC ELECTRIC POWER APPLIED TO UNMANNED AERIAL VEHICLES (UAV)
Jack Geis and Jack H. Arnold (Rockwell International Corp., Canoga Park, CA.) *In* NASA. Lewis Research Center, Proceedings of the 13th Space Photovoltaic Research and Technology Conference (SPRAT 13) Sep. 1994 p 257-268 (For primary document see N95-20502 06-33)
Avail: CASI HC A03/MF A04

Photovoltaic electric-powered flight is receiving a great deal of attention in the context of the United States' Unmanned Aerial Vehicle (UAV) program. This paper addresses some of the enabling technical areas and their potential solutions. Of particular interest are the long-duration, high-altitude class of UAV's whose mission it is to achieve altitudes between 60,000 and 100,000 feet, and to remain at those altitudes for prolonged periods performing various mapping and surveillance activities. Addressed herein are studies which reveal the need for extremely light-weight and efficient solar cells, high-efficiency electric motor-driven propeller modules, and power management and distribution control elements. Since the potential payloads vary dramatically in their power consumption and duty cycles, a typical load profile has been selected to provide commonality for the propulsion power comparisons. Since missions vary widely with respect to ground coverage requirements, from repeated orbiting over a localized target to long-distance routes over irregular terrain, we have also averaged the power requirements for on-board guidance and control power, as well as ground control and communication link utilization. In the context of the national technology reinvestment program, wherever possible we modeled components and materials which have been qualified for space and defense applications, yet are compatible with civilian UAV activities. These include, but are not limited to, solar cell developments, electric storage technology for diurnal operation, local and ground communications, power management and distribution, and control servo design. And finally, the results of tests conducted by Wright Laboratory on ultralight, highly efficient MOCVD GaAs solar cells purchased from EPI Materials Ltd. (EML) of the UK are presented. These cells were also used for modeling the flight characteristics of UAV aircraft. Author (revised)

POST-FLIGHT INVESTIGATION PROGRAMMES OF RECENTLY RETRIEVED SOLAR GENERATORS c44
Lothar Grelach *In* NASA. Lewis Research Center, Proceedings of the 13th Space Photovoltaic Research and Technology Conference (SPRAT 13) Sep. 1994 p 269-283 (For primary document see N95-20502 06-33)
Avail: CASI HC A03/MF A04

In 1993 two ESA solar power generators were successfully retrieved from space: EURECA with its 10 panel rigid array in August, after 11 months in a 500 km orbit, and one of the two flexible Hubble Space Telescope (HST) arrays in December, after almost 4 years in a 600 km orbit. Both solar generators are undergoing separate post-flight investigation programs (PFIP). These programs cover investigations of all solar array (SA) components and mechanisms. Since both programs have much in common, most of the component and material investigations are the same. Extremely valuable information on numerous essential subjects, such as atomic oxygen, radiation, meteoroid and space debris environment resulting damage, low cycle fatigue, material degradation, etc. are expected to be obtained for both types of arrays. We will also be able to explain and understand the anomalies experienced on both solar arrays in orbit. The paper will outline both post-flight investigation programs and will concentrate on reporting the first results and findings. Author (revised)

HIGH-PERFORMANCE, FLEXIBLE, DEPLOYABLE ARRAY DEVELOPMENT FOR SPACE APPLICATIONS

Russell N. Gehling, Joseph H. Armstrong, and Mohan S. Misra *In* NASA. Lewis Research Center, Proceedings of the 13th Space Photovoltaic Research and Technology Conference (SPRAT 13) Sep. 1994 p 287-297 (For primary document see N95-20502 06-33)

Avail: CASI HC A03/MF A04

Flexible, deployable arrays are an attractive alternative to conventional solar arrays for near-term and future space power applications, particularly due to their potential for high specific power and low storage volume. Combined with low-cost flexible thin-film photovoltaics, these arrays have the potential to become an enabling or an enhancing technology for many missions. In order to expedite the acceptance of thin-film photovoltaics for space applications, however, parallel development of flexible photovoltaics and the corresponding deployable structure is essential. Many innovative technologies must be incorporated in these arrays to ensure a significant performance increase over conventional technologies. For example, innovative mechanisms which employ shape memory alloys for storage latches, deployment mechanisms, and array positioning gimbals can be incorporated into flexible array design with significant improvement in the areas of cost, weight, and reliability. This paper discusses recent activities at Martin Marietta regarding the development of flexible, deployable solar array technology. Particular emphasis is placed on the novel use of shape memory alloys for lightweight deployment elements to improve the overall specific power of the array. Array performance projections with flexible thin-film copper-indium-diselenide (CIS) are presented, and government-sponsored solar array programs recently initiated at Martin Marietta through NASA and Air Force Phillips Laboratory are discussed. STATIC STABILITY OF A THREE-DIMENSIONAL SPACE TRUSS c18

John F. Shaker *In its* Proceedings of the 13th Space Photovoltaic Research and Technology Conference (SPRAT 13) Sep. 1994 p 299-312 (For primary document see N95-20502 06-33)

Avail: CASI HC A03/MF A04

Space station requirements for power have resulted in a need for photovoltaic solar arrays possessing large blanket surface area. However, due to the limited shuttle payload volume solar array designers have been driven to a deployable concept that by nature is extremely flexible. The principal support for this array system is the Folding Articulating Square Truss Mast (FASTMast). In order to accomodate service loads the FASTMast is expected to exhibit nonlinear behavior which could possibly result in structural instability. Presented herein are the results of the Lewis Research Center test and analysis efforts performed in an effort to characterize the FASTMast structural behavior in terms of stability. Results include those obtained from recent nonlinear testing and analysis involving a 1/10 segment of the FASTMast flight article. Implications of these results as they relate to expected behavior of the flight unit will also be discussed. Author

AN UPDATE ON THE DEVELOPMENT OF A LINE-FOCUS REFRACTIVE CONCENTRATOR ARRAY c44

Michael F. Piszczor, Mark J. ONeill (ENTECH Corp., Dallas-Fort Worth Airport, TX.), and Lewis M. Fraas (JX Crystals, Issaquah, WA.) *In its* Proceedings of the 13th Space Photovoltaic Research and Technology Conference (SPRAT 13) Sep. 1994 p 313-322 (For primary document see N95-20502 06-33)

Avail: CASI HC A02/MF A04

Concentrator arrays offer a number of generic benefits for space (i.e. high array efficiency, protection from space radiation effects, minimized plasma interactions, etc.). The line-focus refractive concept, however, also offers two very important advantages: (1) relaxation of precise array tracking requirements to only a single axis and (2) low-cost mass production of the lens material. The linear refractive concentrator can be designed to provide an essentially flat response over a wide range of longitudinal errors for satellites having only single-axis tracking capability. New panel designs emphasize light weight, high stiffness, storability, and ease of manufacturing and assembly. This paper addresses the current status of the concentrator program with special emphasis on the design implications, and flexibility, of using a linear refractive concentrator lens as well as details recent fabrication of prototype hardware. RARE EARTH GARNET SELECTIVE EMITTER c76

Roland A. Lowe (Kent State Univ., OH.), Donald L. Chubb, Serene C. Farmer, and Brian S. Good *In its* Proceedings of the 13th Space Photovoltaic Research and Technology Conference (SPRAT 13) Sep. 1994 p 335-339 (For primary document see N95-20502 06-33)

Avail: CASI HC A01/MF A04

Thin film Ho-YAG and Er-YAG emitters with a platinum substrate exhibit high spectral emittance in the emission band (epsilon(sub lambda) approximately equal to 0.74, ((4)I(sub 15/2)) - ((4)I(sub13/2)), for Er-YAG and epsilon(sub lambda) approximately equal to 0.65, ((5)I(sub 7))-((5)I(sub 8)) for Ho-YAG) at excellent candidates for high efficiency selective emitters in the thermophotovoltaics (TPV) systems operating at moderate temperatures (1200-1500K). Spectral emittance measurements of the thin films were made (1.2 less than lambda less than 3.0 microns) and compared to the theoretical emittances calculated using measured values of the spectral extinction coefficient. In this paper we present the results for a new class of rare earth ion selective emitters. These emitters are thin sections (less than 1 mm) of yttrium aluminum garnet (YAG) single crystal with a rare earth substitutional impurity. This paper presents normal spectral emittance, epsilon(sub lambda), measurements of holmium (Ho), and erbium (Er) doped YAG thin film selective emitters at 1500 K, and compares those results with the theoretical spectral emittance. Avail: CASI HC A03/MF A04

Indium gallium arsenide (InGaAs) photovoltaic devices have been fabricated with bandgaps ranging from 0.75 eV to 0.60 on Indium phosphide (InP) substrates. Reported efficiencies have been as high as 11.2 percent (AMO) for the lattice matched 0.75 eV devices. The 0.75 eV cell demonstrated 14.8 percent efficiency under a 1500 K blackbody with a projected efficiency of 29.3 percent. The lattice mismatched devices (0.66 and 0.60 eV) demonstrated measured efficiencies of 8 percent and 6 percent respectively under similar conditions. Low long wavelength response and high rack currents are responsible for the poor performance of the mismatched devices. Temperature coefficients have been measured and are presented for all of the bandgaps tested. Author

PULSED LASER ILLUMINATION OF PHOTOVOLTAIC CELLS c44

Jane A. Yater, Roland A. Lowe (Kent State Univ., OH.), Phillip P. Jenkins (NYMA, Inc., Brook Park, OH.), and Geoffrey A. Landis (NYMA, Inc., Brook Park, OH.) *In its* Proceedings of the 13th Space Photovoltaic Research and Technology Conference (SPRAT 13) Sep. 1994 p 353-362 See also N95-18572 (For primary document see N95-20502 06-33)

Avail: CASI HC A02/MF A04

In future space missions, free electron lasers (FEL) may be used to illuminate photovoltaic array receivers to provide remote power. Both the radio-frequency (RF) and induction FEL provide FEL produce pulsed rather than continuous output. In this work we investigate cell response to pulsed laser light which simulates the RF FEL format. The results indicate that if the pulse repetition is high, cell efficiencies are only slightly reduced compared to constant illumination at the same wavelength. The frequency response of the cells is weak, with both voltage and current outputs essentially dc in nature. Comparison with previous experiments indicates that the RF FEL pulse format yields more efficient photovoltaic conversion than does an induction FEL pulse format. Author

P/N In(Al) GaAs MULTIJUNCTION LASER POWER CONVERTERS c36

Steven Wojtczuk (Spire Corp., Bedford, MA.), Themis Parados (Spire Corp., Bedford, MA.), and Gilbert Walker *In* NASA. Lewis Research Center, Proceedings of the 13th Space Photovoltaic Research and Technology Conference (SPRAT 13) Sep. 1994 p 363-371 (For primary document see N95-20502 06-33)

Avail: CASI HC A02/MF A04

Eight In(Al)GaAs PN junctions grown epitaxially on the semi-insulating wafer were monolithically integrated in series to boost the approximately 0.4V photovoltage per typical In(Al)GaAs junction to over 3 volts for the 1 sq cm laser power converted (LPC) chip. Advantages of multijunction LCP designs include the need for less circuitry for power reconditioning and the potential for lower I(sup 2)R power loss. As an example, these LPC's have a responsivity of approximately 1 amp/watt. With a single junction LPC, 100 watts/sq cm incident power would lead to about 100 A/sq cm short-circuit current at approximately 0.4V open-cicuit voltage. One disadvantage is the large current would lead to a large I(sup 2)R loss which would lower the fill factor so that 40 watts/sq cm output would not be obtained. Another is that few circuits are designed to work at 0.4 volts, so DC-DC power conversion circuitry would be necessary to raise the voltage to a reasonable level. The multijunction LPC being developed in this program is a step toward solving these problems. In the above example, an eight-junction LPC would have eight times the voltage, approximately 3V, so that DC-DC power conversion may not be needed in many instances. In addition, the multijunction LPC would have 1/8 the current of a single-junction LPC, for only 1/64 the I(sup 2)R loss if the series resistance is the same. Working monolithic multijunction laser power converters (LPC's) were made in two different compositions of the In(x)Al(y)Ga(1-x-y)As semiconductor alloy, In(0.53)Ga(0.47)As (0.74 eV) and In(0.5)Al(0.1)Ga(0.4)As (0.87 eV). The final 0.8 sq cm LPC's had output voltages of about 3 volts and output currents up to about one-half amp. Maximum 1.3 micron power conversion efficiencies were approximately 22 percent. One key advantage of multijunction LPC's is that they have higher output voltages, so that less DC-DC power conversion circuitry is needed in applications. Author

HIGH EFFICIENCY GaP POWER CONVERSION FOR BETAVOLTAIC APPLICATIONS

Paul E. Sims, Louis C. DiNetta, and Allen M. Barnett *In* NASA. Lewis Research Center, Proceedings of the 13th Space Photovoltaic Research and Technology Conference (SPRAT 13) Sep. 1994 p 373-382 (For primary document see N95-20502 06-33)

(Grant NSF III-92-61713)

Avail: CASI HC A02/MF A04

AstroPower is developing a gallium phosphide (GaP) based energy converter optimized for radio luminescent light-based power supplies. A 'two-step' or 'indirect' process is used where a phosphor is excited by radioactive decay products to produce light that is then converted to electricity by a photovoltaic energy converter. This indirect conversion of beta-radiation to electrical energy can be realized by applying recent developments in tritium based radio luminescent (RL) light sources in combination with the high conversion efficiencies that can be achieved under low illumination with low leakage, gallium phosphide based devices. This tritium to light approach is inherently safer than battery designs that incorporate high activity radionuclides because the beta particles emitted by tritium are of low average energy and are easily stopped by a thin layer of glass. GaP layers were grown by liquid phase epitaxy and p/n junction devices were fabricated and characterized for low light intensity power conversion. AstroPower has demonstrated the feasibility of the GaP based energy converter with the following key results: 23.54 percent conversion efficiency under 968 muW/sq cm 440 nm blue light, 14.59 percent conversion efficiency for 2.85 muW/sq cm 440 nm blue light, and fabrication of working 5 V array. We have also determined that at least 20 muW/sq cm optical power is available for betavoltaic power systems. Successful developments of this device is an enabling technology for low volume, safe, high voltage, milliwatt power supplies with service lifetimes in excess of 12 years. Author

REVIEW OF SOLAR CELL TEMPERATURE COEFFICIENTS FOR SPACE c44

Geoffrey A. Landis *In* NASA. Lewis Research Center, Proceedings of the 13th Space Photovoltaic Research and Technology Conference (SPRAT 13) Sep. 1994 p 385-399 (For primary document see N95-20502 06-33)

Avail: CASI HC A03/MF A04

Energy conversion efficiency is an important parameter for solar cells, and well reported in the literature. However, solar cells heat up in sunlight, and the efficiency decreases. The temperature coefficient of the conversion efficiency is thus also extremely important, especially in mission modeling, but is much less well reported. It is of value to have a table which compiles into a single document values of temperature coefficients reported in the literature. In addition to modeling performance of solar cells in Earth orbit, where operating temperatures may range from about 20 C to as high as 85 C, it is of interest to model solar cells for several other recently proposed missions. These include use for the surface of Mars, for solar electric propulsion missions that may range from Venus to the Asteroid belt, and for laser-photovoltaic power that may involve laser intensities equivalent several suns. For all of these applications, variations in operating temperature away from the nominal test conditions result in significant changes in operating performance. In general the efficiency change with temperature is non-linear, however, in the range from negative 100 C through room temperature to a few hundred degrees C, efficiency is usually quite well modeled as a linear function of temperature (except for a few unusual cell types, such as amorphous silicon, and for extremely low bandgap cells, such as InGaAs). EFFECTS OF PLASMA HYDROGENATION ON TRAPPING PROPERTIES OF DISLOCATIONS IN HETEROEPITAXIAL InP/GaAs c76

S. A. Ringel and B. Chatterjee *In* NASA. Lewis Research Center, Proceedings of the 13th Space Photovoltaic Research and Technology Conference (SPRAT 13) Sep. 1994 p 401-408 (For primary document see N95-20502 06-33)

(Grant NAG3-1461)

Avail: CASI HC A02/MF A04

In previous work, we have demonstrated the effectiveness of a post-growth hydrogen plasma treatment for passivating the electrical activity of dislocations in metalorganic chemical vapor deposition (MOCVD) grown InP on GaAs substrates by a more than two order of magnitude reduction in deep level concentration and an improvement in reverse bias leakage current by a factor of approximately 20. These results make plasma hydrogenation an extremely promising technique for achieving high efficiency large area and light weight heteroepitaxial InP solar cells for space applications. In this work we investigate the carrier trapping process by dislocations in heteroepitaxial InP/GaAs and the role of hydrogen passivation on this process. It is shown that the charge trapping kinetics of dislocations after hydrogen passivation are significantly altered, approaching point defect-like behavior consistent with a transformation from a high concentration of dislocation-related defect bands within the InP bandgap to a low concentration of individual dislocation related deep levels, before and after passivation. It is further shown that the 'apparent' activation energies of dislocation related deep levels, before and after passivation, reduce by approximately 70 meV as DLTS fill pulse times are increased from 1 microsecond to 1 millisecond. A model is proposed which explains these effects based on a reduction of Coulombic interaction between individual core sites along the dislocation cores by hydrogen incorporation. Knowledge of the trapping properties in these specific structures is important to develop optimum, low loss heteroepitaxial InP cells. Author

We have investigated the early stages of evolution of highly strained 2-D InAs layers and 3-D InAs islands grown by metal-organic chemical vapor deposition (MOCVD) on (100) and (111)B GaAs substrates. The InAs epilayer/GaAs substrate combination has been chosen because the lattice-mismatch is severe (approximately 7.2 percent), yet these materials are otherwise very similar. By examining InAs-on-GaAs composites instead of the more common In(x)Ga(1-x)As alloy we remove an additional degree of freedom (x) and thereby simplify data interpretation. A matrix of experiments is described in which the MOCVD growth parameters - susceptor temperature, Thin flux, and AsH3 flux - have been varied over a wide range. Scanning electron microscopy, atomic force microscopy, transmission electron microscopy, and electron microprobe analysis have been employed to observe the thin film surface morphology. In the case of 3-D growth, we have extracted activation energies and power-dependent exponents that characterize the nucleation process. As a consequence, optimized growth conditions have been identified for depositing approximately 250 A thick (100) and (111)B oriented InAs layers with relatively smooth surfaces. Together with preliminary data on the strain relaxation of these layers, the above results on the evolution of thin InAs films indicate that the (111)B orientation is particularly promising for yielding lattice-mismatched films that are fully relaxed with only misfit dislocations at the epilayer/substrate interface. MOLTEN CARBONATE FUEL CELL PRODUCT DEVELOPMENT TEST
Dec. 1993 75 p
(Contract DE-FC21-92MC-28065)
(DE95-000005; DOE/MC-28065/3880) Avail: CASI HC A04/MF A01

Advanced fuel cell active components have been developed and scaled up from laboratory scale to commercial scale. Full width components of both the stabilized nickel cathodes and the low chrome anodes have been successfully cast on M-C Power's production tape caster. An improved design for a fuel cell separator plate has been developed. The improved design meets the goals of lower cost and manufacturing simplicity, and addresses performance issues of the current commercial area plate. The engineering that the Bechtel Corporation has completed for the MCFC power plant includes a site design, a preliminary site layout, a Process Flow Diagram, and specification for the procurement of some of the major equipment items. Raw materials for anode and cathode components were ordered and received during the first half of 1993. Tape casting of anodes was started in late summer and continued through August. In addition to the technical progress mentioned above, an environment assessment was prepared in compliance with the National Environmental Policy Act of 1969 (NEPA). As a result, the PDT has received a categorical exclusion from the Air Pollution Control District permit requirements. The PDT is configured to demonstrate the viability of natural gas-fueled MCFC for the production of electricity and thermal energy in an environmentally benign manner for use in commercial and industrial applications. CHEMICALLY MODIFIED ELECTRODES Interim Report
Colby A. Foss, Jr. and C. R. Martin 26 May 1994 60 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-82-K-0612)
(AD-A279821; TR-95) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

We learn that the field of chemically-modified electrodes involves attaching specific molecules to the surfaces of conventional inert electrodes. We also discover the two major reasons for wanting to attach molecules to electrode surfaces. One objective is to obtain fundamental information about the mechanism of electron transfer at electrode surfaces. The second objective is to impart to the electrode surface some chemical specificity not available at the unmodified electrode. For example, the modified electrode might catalyze a specific chemical reaction. Alternatively, the modified electrode might be able to recognize a specific molecule present in a contacting solution phase. DTIC

APPLIED PHYSICS RESEARCH FOR INNOVATION IN PULSED POWER Final Report, 1 Jun. 1990 - 30 Jun. 1994
Martin A. Gundersen 30 Sep. 1994 14 p
(Contract N00014-90-J-4074)
(AD-A285392) Avail: CASI HC A03/MF A01

The program addressed fundamental issues in pulsed power technology, emphasizing new GaAs based solid state switches, and new high power thyratron type switches. Results included demonstration of a fast GaAs-based vertical FET-type switch for power modulator, radar and microwave applications, and development of super-emissive cathode switches. Transition of this research to technology is discussed first, then summaries of some of the recent activity are presented. Technology transitions from the research include initiation of a small business in the area of pulsed power technology, substantial impact on modern high power thyratron technology, and impact on the development of solid state devices, including GaAs-based structures. Ongoing work that is related to technology transfer includes development of electron beams for fusion (electron beam ion trap), accelerator and microlithography applications, and development of cathodes with ultra-high emission properties (super-emissive cathode). PROGRESS IN THE DEVELOPMENT OF RECYCLING PROCESSES FOR ELECTRIC VEHICLE BATTERIES
R. G. Jungst and R. P. Clark 1994 10 p Presented at the 12th International Electric Vehicle Symposium, Anaheim, CA, 5-7 Dec. 1994
(Contract DE-AC04-94AL-85000)
(DE94-015894; SAND-94-1944C; CONF-941221-1) Avail: CASI HC A02/MF A01

Disposition of electric vehicle (EV) batteries after they have reached the end of their useful life is an issue that could impede the widespread acceptance of EV's in the commercial market. This is especially true for advanced battery systems where working recycling processes have not as yet been established. The DOE sponsors an Ad Hoc Electric Vehicle Battery Readiness Working Group to identify barriers to the introduction of commercial EV's and to advise them of specific issues related to battery reclamation/recycling, in-vehicle battery safety, and battery shipping. A Sub-Working Group on the reclamation/recycle topic has been reviewing the status of recycling process development for the principal battery technologies that are candidates for EV use from the near-term to the long-term. Recycling of near-term battery technologies, such as lead-acid and nickel/cadmium, is occurring today and it is believed that sufficient processing capacity can be maintained to keep up with the large number of units that could result from extensive EV use. Reclamation/recycle processes for midterm batteries are partially developed. Good progress has been made in identifying processes to recycle sodium/sulfur batteries at a reasonable cost and pilot scale facilities are being tested or planned. A pre-feasibility cost study on the nickel/metal hydride battery also indicates favorable economics for some of the proposed reclamation processes. Long-term battery technologies, including lithium-polymer and lithium/iron disulfide, are still being designed and developed for EV's, so descriptions for prototype recycling processes are rather general at this point. Due to the long time required to set up new, full-scale recycling facilities, it is important to develop a reclamation/recycling process in parallel with the battery technologies themselves. DOE

DEVELOPMENT OF A TESTER FOR EVALUATION OF PROTOTYPE THERMAL CELLS AND BATTERIES

Ronald A. Guidotti 1994 7 p Presented at the 10th Annual Battery Conference on Applications and Advances, Long Beach, CA, 10-13 Jan. 1995
(Contract DE-AC04-94AL-85000)
(DE95-000540; SAND-94-2472C; CONF-950121-1) Avail: CASI HC A02/MF A01

A tester was developed to evaluate prototype thermal cells and batteries--especially high-voltage units--under a wide range of constant-current and constant-resistance discharge conditions. Programming of the steady-state and pulsing conditions was by software control or by hardware control via an external pulse generator. The tester was assembled from primarily Hewlett-Packard (H-P) instrumentation and was operated under H-P's Rocky Mountain Basic (RMB). Constant-current electronic loads rated up to 4 kW (400 V at up to 100 A) were successfully used with the setup. For testing under constant-resistance conditions, power metal-oxide field-effect transistors (MOSFET's) controlled by a programmable pulse generator were used to switch between steady-state and pulse loads. The pulses were digitized at up to a 50 kHz rate (20 microseconds/pt) using high-speed DVM's; steady-state voltages were monitored with standard DVM's. This paper describes several of the test configurations used and discusses the limitations of each. Representative data are presented for a number of the test conditions. DOE

FIELD-EMITTER ARRAYS FOR RF VACUUM MICROELECTRONICS Quarterly Technical Report No. 10, 1 Jan. - 31 Mar. 1994

C. A. Spindt 31 May 1994 17 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract MDA972-91-C-0029; ARPA Order 8162)
(AD-A279959) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

SRI International has completed the tenth quarter of a program to develop field-emitter arrays for vacuum microelectronics. We have met the first-phase program goals of 5 mA total emission, with a current density of 5 A/sq cm for at least 2 hours and demonstrated modulation of the emission current at a frequency of 1 GHz. Principal efforts involved the development of a process for forming emitter cones in small diameter apertures and with improved aspect ratios to reduce stress accumulation on film, modification of reactive ion etching chemistry to eliminate sulfur contamination of the cathode, investigation of galvanic etching resulting from a deionized-water rinse, and methods of fabricating emitters arrays with increased geometric field-enhancement factors and higher packaging densities. Variations in emission test results in cathodes at SRI and in cathodes given high-frequency tests at NRL were investigated, and an emission microscope for use in studying emitter array performance, yield, and reliability was assembled. ELASTOMERIC ELECTRICAL CONNECTOR Patent

Joseph E. Laska, inventor (to Navy), John T. Oakley, inventor (to Navy), and Francis R. Reinert, inventor (to Navy) 27 Sep. 1994 8 p Filed 16 Aug. 1993 Supersedes AD-D016340
(AD-D016559; US-Patent-5,350,308; US-Patent-Appl-SN-107431; US-Patent-Class-439-91) Avail: US Patent and Trademark Office

This is an elastic device that provides solderless, pressure contact, electrical connections between leads or leads and terminals at an interface. The elastic device comprises elastomeric material, such as silicone rubber, and has electrical conductive, compressible wires formed of a metal, such as monel, embedded in the silicone. The elastic device is particularly suited to provide electrical connections between an interface that is brought together by a connector and which is separable in response to an impulse that may be created by an explosion produced by a pyrotechnic device. SOFTWARE FOR FLOW DISTRIBUTION IN ELECTRONIC RACK STRUCTURES Final Report, 1 Oct. 1993 - 30 Sep. 1994

Ron J. Pieper 1 Sep. 1994 48 p
(AD-A285994; NPSEC-94-010) Avail: CASI HC A03/MF A01

A FORTRAN CODE has been developed which predicts pressures and flow rates in a piping network for the regimes of laminar, transition, and turbulent flow. A novel and effective scheme for modeling the transition region between laminar and turbulent flow is demonstrated. A proposed linear indicator for the deviation from laminar behavior is introduced into the analysis in order to facilitate the computational task. Although the turbulent flow problem is inherently nonlinear, the method of analysis described herein, typically employed with linear electrical networks, is found to converge rapidly to an approximate solution without user-specified a priori guesses. METHOD OF FABRICATING A MICROELECTRONIC PHOTOMULTIPLIER DEVICE WITH INTEGRATED CIRCUITRY Patent

Randy L. Shimabukuro, inventor (to Navy) and Stephen D. Russell, inventor (to Navy) 12 Jul. 1994 12 p Filed 22 Nov. 1993
(AD-D016530; US-Patent-5,329,110; US-Patent-Appl-SN-156192; US-Patent-Class-250-207) Avail: US Patent and Trademark Office

A microelectronic photomultiplier device is fabricated by discrete procedures to provide a photocathode-anode and dynode chain arrangement which is analogous in operation to conventional photomultiplier tubes. This microelectronic photomultiplier device provides for low level photon detection and realizes the advantages of high reliability, small size and fast response, plus lower cost, weight and power consumption compared to conventional photomultiplier tubes. In addition, the fabrication on an SOI substrate permits integration of logic and control circuitry with detectors. The insulating substrate also permits the integration of an on-chip high voltage supply and may easily be extended to a plurality of detectors offering improved performance and design flexibility. DTIC

N95-20727 Department of the Navy, Washington, DC.

MICRODYNAMIC DEVICES FABRICATED ON SILICON-ON-SAPPHIRE SUBSTRATES Patent

Douglas A. Sexton, inventor (to Navy) 19 Jul. 1994 5 p Filed 19 Aug. 1992
(AD-D016531; US-Patent-5,331,236; US-Patent-Appl-SN-932430; US-Patent-Class-310-40) Avail: US Patent and Trademark Office

Silicon-on-sapphire substrates are provided for the fabrication of micromechanical devices, such as micromotors. The high voltage stand-off characteristics of silicon-on-sapphire thereby provides for the construction of superior electrostatically driven devices and sensors capable of being driven at significantly higher applied potentials since silicon-on-sapphire has demonstrated a capability for building in the range of hundreds of Angstroms, or thick, in the range of microns very high speed, low power, very densely packed integrated circuits using standard silicon processing techniques. As a consequence, the electrostatically driven devices, micromotors, can be incorporated in the integrated circuits and yet be powered at elevated voltages to increase their work potential. DTIC

N95-20729 Department of the Navy, Washington, DC.
HIGH ISOLATION ELECTRONIC SWITCH Patent
Thomas I. Kirkpatrick, inventor (to Navy) 2 Aug. 1994 6 p Filed 19 Mar. 1992
(AD-D016533; US-Patent-5,334,881; US-Patent-Appl-SN-854112; US-Patent-Class-307-241) Avail: US Patent and Trademark Office

A high isolation electronic switch is provided for selectively switching an output line between first and second input lines. Each input line is connected to a respective circuit that has a first current carrying path to connect the respective input line to the output line, and a second current carrying path to connect a portion of the first current carrying path of the respective circuit to a ground potential. Each respective circuit is further selectively operated to conduct along only one of its first or second current carrying paths. A unity gain buffer is connected serially in the first current carrying path of each respective circuit. The switch is selectively operated such that one circuit conducts along its first current carrying path when the other circuit is conducting along its second current carrying path. DTIC

HYBRID HIGH POWER AMPLIFIER Patent
Russell E. Hammond, inventor (to Navy) and Leopold J. Johnson, inventor (to Navy) 12 Jul. 1994 9 p Filed 28 Jun. 1993
(AD-D016534; US-Patent-5,329,245; US-Patent-Appl-SN-086079; US-Patent-Class-330-251) Avail: US Patent and Trademark Office

The invention provides a high power, low distortion, high efficiency amplifier design incorporating a high efficiency switching amplifier used in conjunction with a linear difference amplifier. The high efficiency switching amplifier, typically of full or half bridge design, is designed to generate a high efficiency, arbitrarily formed, wave portion such as a square wave. The high efficiency waveform is scaled down and is compared to a desired reference, such as a sinusoid. The output of the comparison is the analog difference (mathematical subtraction) between the reference waveform and the scaled-down switch amplifier output wave. This difference signal is then used to drive the linear difference amplifier which simply scales the signal linearly. The two power signals, one from the switching amplifier and the other from the linear difference amplifier, are then summed magnetically. To permit a low harmonic output, the input signals to the switching amplifier and the reference are locked together in frequency. DTIC

MAGNETRON POWER SUPPLY AT HIGH STABILITY AND ITS APPLICATION IN PLASMA EXCITATION FOR THE PRODUCTION OF ULTRAVIOLET RADIATION Ph.D. Thesis [ALIMENTATION DU MAGNETRON A HAUTE STABILITE ET APPLICATION A L'EXCITATION DE PLASMAS POUR LA GENERATION DE RAYONNEMENT ULTRAVIOLET]
J. O. PachecoSotelo 1993 143 p In FRENCH
(DE94-629656; INIS-MF-13929) Avail: CASI HC A07/MF A02 (US Sales Only)

This work describes the combination of different disciplines which allow the development of a microwave generator with capacity for power control and stabilization frequency. This generator is used for plasma excitation in partially filled mercury lamps and for the production of ultraviolet radiation. By now, resonance techniques lead to a lot of researches. For our part we used a resonance converter as a magnetron power supply, exploiting its inherent characteristic of current limitation to protect the magnetron. The power is controlled by varying the frequency of the converter. The implementation of several electronic systems for the detection and control of the power and microwave frequency was made, in order to get an optimum dynamic behaviour. For the optimum transfer in energy, from the source (microwave generator) to the load (mercury lamp), a special resonator was implemented. This resonator allow UV radiation, at the same time avoiding the leakage of microwave energy. Finally, this work shows the advantages of the UV radiation through microwave discharge in comparison to conventional methods. DOE

EFFECT OF A SOLID INSULATOR ON THE SPARK YIELD OF S2F10 IN SF6(*)
I. Sauers, S. M. Mahajan, and R. A. Cacheiro 1994 4 p Presented at the IEEE International Symposium on Electrical Insulation, Pittsburgh, PA, 5-8 Jun. 1994
(Contract DE-AC05-84OR-21400)
(DE95-001422; CONF-940671-1) Avail: CASI HC A01/MF A01

Because of its toxicity S2F10 production in SF6 discharges has been the focus of intensive study in recent years. In previous work we have examined the yield of S 2F10 for corona, spark and arc discharges and, in sparks, the effects of water and oxygen have been studied systematically. Here we report the influence of an insulating solid spacer on the production of S2F10 in SF6 when subjected to spark discharges in the energy range 1.6-43 J/spark at a gas pressure of 1 atm. Analyses of the sparked gases were performed using a cryogenic enrichment gas chromatography technique with a sensitivity of less than 10 ppb (parts-per-billion) or 1 in 10(exp 8). With this sensitivity S2F10 can be detected after one or just a few spark(s), minimizing secondary effects of gas contamination, electrode erosion and insulator damage that can influence S2F10 production and make quantitative yield determinations difficult to establish. For these studies Teflon was used as the spacer sandwiched between two stainless steel electrodes. Energy measurements were made after recording the voltage and current waveforms. The amount of S2F10 produced per unit energy deposited into the discharge was found to be greater in the presence of the spacer than for a purely gas gap. Factors which influence S2F10 stability such as surfaces and water will also b e discussed. DOE

NICKEL HYDROXIDE ELECTRODES IN REDUCED-ALKALINITY ELECTROLYTES Ph.D. Thesis
Robert F. Plivelich Apr. 1994 81 p
(Contract DE-AC03-76SF-00098)
(DE95-002333; LBL-35628) Avail: CASI HC A05/MF A01

Nickel oxide electrodes cycled to failure in zinc-nickel oxide cells were studied. These cells incorporated novel electrolytes intended to increase the Zinc electrode cycle life. The Zinc species deposited in the failed Ni electrodes was probably ZnOH2 or ZnO. Evidence was found for a strictly mechanical interpretation of the capacity degradation of the Nickel oxide electrodes. The gas evolution in failure of Nickel electrodes in the zinc-nickel oxide system using a reduced-alkalinity electrolyte, needs to be studied. DOE

HIGH PERFORMANCE YBCO FILMS Report, 25 Aug. 1994 - 25 Nov. 1995
Edgar J. Denlinger, Aly Fathy, David Kalokitis, Valerie Pendrick, and Barry Thaler 25 Aug. 1994 7 p
(Contract N00014-91-C-0216)
(AD-A286567) Avail: CASI HC A02/MF A01

The focus for the remainder of our program, which will end during the next quarter, is on oxygen annealing the buried YBCO ground plane through the Ag power plane and glass/metal handle as well as making an MCM structure with YBCO being used for only the signal layer. Oxygen annealing of a YBCO-covered lanthanum aluminate through five microns of thermally evaporated silver, after subjecting the sample to glass-firing conditions, recovered the microwave Q of the sample to within 16-18% of its original value (measured before the silver was deposited). The oxygen annealing time was only 4 hours. This Q degradation is believed to be acceptable for the YBCO ground plane of an MCM module. Addition of the STO dielectric layer between the YBCO ground plane and the silver makes the oxygen annealing time very long (greater than 18 hours). DTIC

BRIEF TUTORIAL ON THE KALMAN FILTER Annual Report, Sep. - Nov. 1991
John Podesta Nov. 1994 32 p
(AD-A286571; ARFSD-SP-94001) Avail: CASI HC A03/MF A01

A derivation of the Kalman filter equations is presented which should provide a concise introduction to Kalman filter theory for scientists, engineers, and mathematicians alike. An elementary derivation of the basic Kalman filter, the 1-step Kalman predictor, is given first in 1-dimension and then in n-dimension. The well known prediction-correction formulation of the Kalman filter equations are derived for the filtered estimate, or current state estimate. Then, the state prediction is obtained from the filtered estimate. It is assumed that the reader has a background in probability theory and some exposure to stochastic processes. DTIC

LLNL/LION PRECISION LVDT AMPLIFIER
D. J. Hopkins Apr. 1994 8 p Presented at the American Society for Precision Engineering (ASPE) Conference, Tucson, AZ, 6-8 Apr. 1994
(Contract W-7405-eng-48)
(DE95-001504; UCRL-JC-116930; CONF-9404131-3) Avail: CASI HC A02/MF A01

A high-precision, low-noise, LVDT amplifier has been developed which is a significant advancement on the current state of the art in contact displacement measurement. This amplifier offers the dynamic range of a typical LVDT probe but with a resolution that rivals that of non contact displacement measuring systems such as capacitance gauges and laser interferometers. Resolution of 0.1 (mu) in with 100 Hz bandwidth is possible. This level of resolution is over an order of magnitude greater than what is now commercially available. A front panel switch can reduce the bandwidth to 2.5 Hz and attain a resolution of 0.025 (mu) in. This level of resolution meets or exceeds that of displacement measuring laser interferometry or capacitance gauge systems. Contact displacement measurement offers high part spatial resolution and therefore can measure not only part contour but surface finish. Capacitance gauges and displacement laser interferometry offer poor part spatial resolution and can not provide good surface finish measurements. Machine tool builders, meteorologists and quality inspection departments can immediately utilize the higher accuracy and capabilities that this amplifier offers. The precision manufacturing industry can improve as a result of improved capability to measure parts that help reduce costs and minimize material waste. DOE

COMPLEMENTARY GaAs JUNCTION-GATED HETEROSTRUCTURE FIELD EFFECT TRANSISTOR FABRICATION FOR INTEGRATED CIRCUITS
A. G. Baca, J. C. Zolper, M. E. Sherwin, P. J. Robertson, R. J. Shul, A. J. Howard, D. J. Rieger, and J. F. Klem 1994 10 p Presented at the 186th Meeting of the Electrochemical Society, Miami, FL, 9-14 Oct. 1994
(Contract DE-AC04-94AL-85000)
(DE95-001522; SAND-94-1670C; CONF-941063-7) Avail: CASI HC A02/MF A01

A new GaAs junction-gated complementary logic technology that integrates a modulation doped p-channel heterostructure field effect transistor (pHFET) and a fully ion implanted n-channel JFET has recently been fabricated. High-speed, low-power operation has been demonstrated with loaded ring oscillators that show gate delays of 179 ps/stage for a power-delay product of 28 fJ at 1.2 V operation and 320 ps/stage and 8.9 fJ at 0.8 V operation. The principal advantages of this technology include the ability to independently set the threshold voltage of n- and p-channel devices and to independently design the pHFET for high performance. A self-aligned refractory gate process based on tungsten and tungsten silicide gate metal has been used to fabricate the FETs. Novel aspects of the fabrication include the simultaneous formation of non-alloyed, refractory ohmic contacts for the junction gates and the formation of shallow p-n junctions by ion implantation. TECHNOLOGIES FOR HIGHLY PARALLEL OPTOELECTRONIC INTEGRATED CIRCUITS
K. L. Lear 1994 6 p Presented at the GaAs Symposium, Philadelphia, PA, 16-19 Oct. 1994
(Contract DE-AC04-94AL-85000)
(DE95-001607; SAND-94-2349C; CONF-9410195-2) Avail: CASI HC A02/MF A01

While summarily reviewing the range of optoelectronic integrated circuits (OEIC's), this paper emphasizes technology for highly parallel optical interconnections. Market volume and integration suitability considerations highlight board-to-board interconnects within systems as an initial insertion point for large OEIC production. The large channel count of these intrasystem interconnects necessitates two-dimensional laser transmitter and photoreceiver arrays. Surface normal optoelectronic components are promoted as a basis for OEIC's in this application. An example system is discussed that uses vertical cavity surface emitting lasers for optical buses between layers of stacked multichip modules. Another potentially important application for highly parallel OEIC's is optical routing or packet switching, and examples of such systems based on smart pixels are presented. DOE

DEVELOPMENT OF AN ANNULAR ELECTRON BEAM HPM AMPLIFIER Final Report, Aug. 1991 - Jan. 1994
Kyle J. Hendricks, Walter R. Fayne, Thomas A. Spencer, Lester A. Bowers, and M. J. Arman Sep. 1994 70 p
(AD-A286646; PL-TR-94-1065) Avail: CASI HC A04/MF A01

Experiments and computer simulations of annular electron beam powered microwave devices have been conducted, This work included the generation of an annular electron beam using the IMP pulser, the modulation of this beam via a two-cavity klystron-like amplifier, and the extraction or radiation of the microwave power. Results of computer simulations from several codes used to design the experiments and results of experiments on propagating the electron beam, injecting a magnetron signal into the two-cavity klystron-like amplifier via a vacuum coaxial line, and initial work on modulating the electron beam are presented. THE OPPORTUNITIES FOR AND CHALLENGES OF COMMON INTEGRATED ELECTRONICS Final Report, Jul. - Dec. 1993
J. R. Nelson, Bernard L. Retterer, and Harley A. Cloud Feb. 1994 40 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract MDA903-89-C-0003)
(AD-A279991; IDA-D-1490; IDA/HQ-93-44599; AD-E501787) Avail: CASI HC A03

This document summarizes a portion of IDA's work concerning common integrated electronics and the potential cost savings of using common electronic hardware and software. It addresses trends in avionics costs and recent experiences in applying common electronic standards to weapon programs as a way to reduce costs. The following essential elements of a program to acquire common integrated electronics are explored: (1) integrated system architecture; (2) advanced technology programs; (3) open system standards; (4) standard common modules; and (5) associated management and policies. The principal recommendation is that OSD support and coordinate such a-program by taking a strong leadership role and setting standards policy. DTIC

(AD-A280065; RL-TR-94-23) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This report describes the development and application of parametric and geometry based macro-models of hot-carrier induced dynamic degradation in MOS VLSI circuits. Previously, a simulation based approach has been used for reliability analysis, but this is inefficient for reliability assessment of very large scale integrated circuits. Geometry-based macro-models for hot-carrier reliability estimation have been developed. The macro-models express hot-carrier damage as functions of designable parameters such as transistor size (W), output loading capacitance (C1) and the input signal slew rate (a). A prototype rule-based reliability diagnosis tool, iRULE, has been developed. This tool uses the macro-models for designing hot-carrier resistant circuits without the need for transient reliability simulations. This provides the ability to analyze very large circuits with more than one million transistors on a workstation in a short amount of time. This report also describes a fast timing reliability simulation tool, ILLIADS-R, that can accurately estimate hot-carrier degradation while providing several orders of magnitude speed up over traditional transistor-level circuit simulators. AN AUTOMATIC PLACEMENT TOOL FOR RAPID PROTOTYPING OF PRINTED CIRCUIT BOARDS
John Granacki and Tauseef Kazi Nov. 1993 24 p
(AD-A286029; ISI/RR-93-388) Avail: CASI HC A03/MF A01

This report describes a fully automatic placement tool for PCB's (printed circuit boards), nap (nonhierarchical automatic placement) that combines approaches from different placement heuristics developed both for PCB and VLSI chip placement. Although the problem of placement for a PCB can be abstractly cast into the same formalism as the problem of VLSI cell placement, a practical tool must incorporate many additional features. In this report we describe the impact of incorporating these PCB-specific features as well as other constraints imposed by the CAD environment (that is, the schematic capture system and the automatic routing tools) into an automatic placement tool. Next we discuss the selected heuristics and their associated data structures in detail. Following this discussion, we present the results of using the placement tool on two test cases along with an analysis of the tools performance. Finally, we identify the limitations of the current implementation and we propose some possible solutions and future work. DTIC

The formation energy for mercury vacancy - tellurium antisite pairs is calculated. We developed a method for calculating the ionization energies of the defects in semiconductors. The electron-phonon interaction-induced band-edge shifts in semiconductors are calculated using accurate band structures. The temperature variation of gaps in GaAs (done to validate our method) and Hg(0.78)Cd(0.22)Te have been calculated and are found to agree well with experiments. DTIC

TRANSDUCERS WITH IMPROVED SIGNAL TRANSFER FIELD OF THE INVENTION Patent Application
Chulo Kim, inventor (to Navy) and Manfred Kahn, inventor (to Navy) 25 Jan. 1994 31 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-D016228; US-Patent-Appl-SN-193686) Avail: CASI HC A03

A transducer includes a rigid resin in the form of a solid block; a plurality of spaced and parallel piezoelectric rods of equal length disposed in the rigid resin and extending at one end thereof beyond the rigid resin; a solid soft resin enveloping the rods; and electrically conducting cover plates disposed against extremities of the rods; the rigid resin block being composed of a plurality of stacked preforms having spaced and parallel upper grooves wherein the rods are disposed. The process for making transducers with extended piezoelectric rods includes the steps of loading the rods into a plurality of spaced and parallel upper grooves of preforms made from a rigid resin; stacking the loaded preforms one on top of another to the desired height, the rods being flush with the preforms at one end and extending beyond the preforms at the other end; infiltrating a soft resin around the rods; curing the soft resin to a solid, compressible state; and applying electrically conducting cover plates against the rod ends. FIBER-OPTIC CONTROL OF CURRENT FILAMENTS IN HIGH GAIN PHOTOCONDUCTIVE SEMICONDUCTOR SWITCHES
F. J. Zutavern, G. M. Loubriel, W. D. Helgeson, M. W. OMalley, R. R. Gallegos, A. G. Baca, T. A. Plut, and H. P. Hjalmarson 1994 4 p
Presented at the 21st International Power Modulator Symposium, Costa Mesa, CA, 28-30 Jun. 1994
(Contract DE-AC04-94AL-85000)
(DE94-015804; SAND-94-0428C; CONF-940678-7) Avail: CASI HC A01/MF A01

The discovery of current filaments in GaAs photoconductive semiconductor switches (PCSS) raised concerns about the location and density of the current distribution during high gain switching. This paper describes experiments using fiber-optic coupled laser diode arrays (LDA) to control the location and number of current filaments in GaAs PCSS. Infrared (IR) images of the recombination radiation, that is emitted from the surface of the PCSS, show precisely where the current is concentrated. These were recorded as the fiber-optic configuration and switch test parameters were varied. Up to twenty individually-coupled laser diodes and fibers were used to initiate multiple, simultaneous filaments. Fibers were configured in a row both parallel and perpendicular to the direction of current. Two types of experiments were performed: high current; and high voltage. System impedances of 0.25 Omega and 50 Omega were used with switch currents up to 5.2 kA and initial charging voltages up to 100 kV, respectively. Switch sizes were 1 x 5 sq mm and 15 x 38 sq mm (parallel x perpendicular to the current). With the 0.25 Omega system charged to 4 kV (40 kV/cm across the PCSS), individual filaments were triggered with 150 nJ of optical trigger energy. In this case, filaments were triggered at both ends near the contacts with pairs of 250 micro m fibers, each ofwhich delivered 75 nJ in 140 ps. The use of multiple fiber pairs to distribute the current more uniformly across the switch improved switch performance. It allowed higher total currents to be switched with narrower switches. With the 50 Omega system charged to 100 kV (67 kV/cm across the PCSS), individual filaments were triggered with as little as 90 nJ of optical trigger energy. The trigger pulse was delivered in 2 ns through one fiber which was 400 micro m in diameter. DOE

GEOMETRIC CHARACTERIZATION OF ELECTROMIGRATION VOIDS (A STATISTICAL ANALYSIS OF ELECTROMIGRATION VOIDS) Final Report, Jun. 1993 - Sep. 1994
Yolanda J. Kime and Peter Grach Oct. 1994 13 p
(Contract F30602-93-C-0167)
(AD-A286494; RL-TR-94-190) Avail: CASI HC A03/MF A01

The areas, perimeters, lengths, and widths of 998 electromigration induced voids on 38 test stripes have been measured by SEM and digital image analysis. Virtually all of the voids occurred along the passivation-conductor interface on the side of the stripe. A plot of the number of voids on each stripe versus time to failure does not extrapolate to zero at zero time to failure, which suggests there are a certain number of active sites predisposed to voiding. EFFECTS OF BATTERY TECHNOLOGIES, DRIVING PATTERNS, AND CLIMATE COMFORT CONTROL ON THE PERFORMANCE OF ELECTRIC VEHICLES
William W. Marr, Michael Q. Wang, and Danilo J. Santini 15 May 1994 7 p Presented at the Electric, Hybrid and Alternative Fuel Vehicles Conference, Aachen, Germany, 31 Oct. - 4 Nov. 1994
(Contract W-31-109-eng-38)
(DE95-001102; ANL/ES/CP-82395; CONF-9410221-2) Avail: CASI HC A02/MF A01

A computer software package, EAGLES, has been developed at Argonne National Laboratory to analyze electric vehicle (EV) performance. In this paper, we present EAGLES predictions of EV driving range, acceleration rate, and energy consumption under various driving patterns, with different battery technologies, and with assumptions concerning use of air conditioners and/or heaters for climate comfort control. The specifications of a baseline, four-passenger EV for given design performance requirements are established, assuming urban driving conditions represented by the Los Angeles 92 (LA-92) driving cycle and using battery characteristics similar to those of the United States Advanced Battery Consortium (USABC) midterm battery performance goals. To examine the impacts of driving patterns, energy consumption is simulated under three different driving cycles: the New York City Cycle, the Los Angeles 92 Cycle, and the ECE-15 Cycle. To test the impacts of battery technologies, performance attributes of an advanced lead-acid battery, the USABC midterm battery goals, and the USABC long-term battery goals are used. Finally, EV energy consumption from use of air conditioners and/or heaters under different climates is estimated and the associated driving range penalty for one European city (Paris) and two United States cities (Chicago and Los Angeles) is predicted. The results of this paper show the importance of considering various effects, such as battery technology, driving pattern, and climate comfort control, in the determination of EV performances. Electric vehicle energy consumption decreases more than 20% when a battery with characteristics similar to the USABC long-term goals is used instead of an advanced lead-acid battery. DOE

SURVIVABILITY OF SOLDERED LEADLESS CHIP CARRIERS AFTER TEMPERATURE CYCLING
L. R. Zawicki, B. W. Lenhardt, and F. R. Smith Sep. 1994 6 p Presented at the Meeting on the Revolution in Microelectronics, Boston, MA, 15-17 Nov. 1994
(Contract DE-AC04-76DP-00613)
(DE95-001497; KCP-613-5388; CONF-941199-3) Avail: CASI HC A02/MF A01

Temperature cycling evaluations were conducted on leadless chip carriers (LCC's) soldered to thick film networks (TKN's). Various temperature ranges, rates of change, cycle times, number of cycles, and sizes of LCC's were used. The TKN's were attached to metal backing plates with 63Sn/37Pb solder preforms using an infrared vacuum soldering process. The LCC's were attached to Pt/Au TKN's with 63Sn/37Pb solder paste using a belt reflow process. Visual examination and cross-sectional analysis were used to evaluate the survivability. Results were also correlated with finite elemental analysis. Considering the initial results, possible solutions included changing the solder from 63Sn/37Pb to 50Pb/50In, deleting the metal backplate, changing the rate of change in the temperature cycle, and/or adding leads to the large LCC's. Because of a system requirement, the rate of change in the temperature cycle could not be changed. Since there was no long term reliability information on the Pt/Au TKN with 50Pb/50In solder, this option was also dropped. Additional evaluations showed little difference in the survivability of large LCC solder joints with or without the metal backing plate. The final results indicated that LCC's beyond a certain physical size required compliant leads to survive the temperature cycle requirements. DOE

EQUIVALENT SOURCE CURRENT FORMULATION IN IMPEDANCE TOMOGRAPHY
Risto J. Ilmoniemi (Helsinki Univ. Central Hospital, Helsinki, Finland.) and Seppo P. Ahlfors Apr. 1994 15 p
(ISSN 0355-7790)
(PB95-127627; TKK-F-A728; ISBN-951-22-2122-5) Avail: CASI HC A03/MF A01

Changes in the conductivity distribution of a body modify the electromagnetic field due to injected current in the same way as an equivalent source current distribution J(sup eq)(r) does. In the limit of small perturbations, it is shown that J(sup eq)(r) = Sigma(sup 1)(r)E(sup 0)(r), where Sigma(sup 1)(r) is a deviation in the conductivity and E(sup 0)(r) is the non-perturbed electric field. A model experiment demonstrates how a conductivity anomaly can be located using the minimum-norm estimate of the equivalent currents. The minimum-norm solution for small perturbation Sigma(sup 1)(r) is derived as well. The equivalent-source formulation allows the direct application of biomagnetic and bioelectric source-determination methods to conductivity imaging. NTIS

SPECTROSCOPIC, MORPHOLOGICAL, AND ELECTRICAL CHARACTERIZATION OF PdGe OHMIC CONTACTS TO n-GaAs
A. J. Howard, M. L. Lovejoy, K. R. Zavadil, D. J. Rieger, R. J. Shul, J. C. Zolper, and P. A. Barnes (Auburn Univ., AL.) 1994 6 p Presented at the Topical Conference on the Synthesis and Processing of Electronic Materials, San Francisco, CA, 13-18 Nov. 1994
(Contract DE-AC04-94AL-85000)
(DE95-000738; SAND-94-2201C; CONF-9411132-1) Avail: CASI HC A02/MF A01

Novel material systems such as ZnS(y)Se(1-y) and Zn(x)Cd(1-x)Te that are commonly grown at low temperatures (approximately 300 C), require unique, low temperature processing schemes. For example, ohmic contact formation with the common AuGeNi n-GaAs contact is not appropriate for this application due to its relatively high anneal temperature (approximately 400 C). For this reason, we investigated the effects of anneal temperature (150 to 400 C) and time (5 to 30 min) on the contact resistivity of PdGe to n-GaAs substrates. The contact surface morphology was measured by AFM and the material composition profile was analyzed by XPS. The characteristics of the PdGe contact are compared to the standard AuGeNi n-GaAs contact. DOE

THEORY AND MODELLING OF QUENCH IN CABLE-IN-CONDUIT SUPERCONDUCTING MAGNETS Ph.D. Thesis
A. Shajii Apr. 1994 267 p
(Contracts DE-FC02-93ER-54186; DE-AC07-76ID-01570)
(DE95-001819; PFC/RR-94-5; DOE/ER-54186/T4) Avail: CASI HC A12/MF A03

A new simple, self consistent theoretical model is presented that describes the phenomena of quench propagation in cable-in-conduit superconducting magnets. The model (Quencher) circumvents many of the difficulties associated with obtaining numerical solutions in more general existing models. Specifically, a factor of 30-50 is gained in CPU time over the general, explicit time dependent codes used to study typical quench events. The corresponding numerical implementation of the new model is described and the numerical results are shown to agree very well with those of the more general models, as well as with experimental data. Further, well justified approximations lead to the MacQuench model that is shown to be very accurate and considerably more efficient than the Quencher model. The MacQuench code is suitable for performing quench studies on a personal computer, requiring only several minutes of CPU time. In order to perform parametric studies on new conductor designs it is required to utilize a model such as MacQuench because of the high computational efficiency of this model. Finally, a set of analytic solutions for the problem of quench propagation in cable-in-conduit conductors is presented. These analytic solutions represent the first such results that remain valid for the long time scales of interest during a quench process. The assumptions and the resulting simplifications that lead to the analytic solutions are discussed, and the regimes of validity of the various approximations are specified. The predictions of the analytic results are shown to be in very good agreement with numerical as well as experimental results. Important analytic scaling relations are verified by such comparisons, and the consequences of some of these scalings on currently designed superconducting magnets are discussed. DOE

PERFORMANCE TESTING OF THE AC PROPULSION ELX ELECTRIC VEHICLE
W. E. Kramer, R. D. MacDowall, and A. F. Burke Jun. 1994 141 p
(Contract DE-AC07-76ID-01570)
(DE95-002049; EGG-EP-11320) Avail: CASI HC A07/MF A02

Performance testing of the AC Propulsion ELX electric vehicle is described. Test data are presented and analyzed. The ELX vehicle is the first of a series of electric vehicles of interest to the California Air Resources Board. The test series is being conducted under a Cooperative Research and Development Agreement (CRADA) between the US Department of energy and the California Air Resources Board. The tests which were conducted showed that the AC Propulsion ELX electric vehicle has exceptional acceleration and range performance. When the vehicle's battery was fully charged, the vehicle can accelerate from 0 to 96 km/h in about 10 seconds. Energy consumption and range tests using consecutive FUDS and HWFET Driving cycles (the all-electric cycle) indicate that the energy economy of the AC Propulsion ELX electric vehicle with regenerative braking is 97 W(center dot)h/km, with a range of 153 km (95 miles). Computer simulations performed using the SIMPLEV Program indicate that the vehicle would have a range of 327 km (203 miles) on the all-electric cycle if the lead acid batteries were replaced with NiMH batteries having an energy density of 67 W(center dot)h/kg. Comparisons of FUDS test data with and without regenerative braking indicated that regenerative braking reduced the energy consumption of the ELX vehicle by approximately 25%. DOE

ELECTRICAL IMPEDANCE STUDIES OF ACID-FORM NAFION MEMBRANES Interim Technical Report, Apr. 1993 - May 1994
J. J. Fontanella, M. G. McLin, M. C. Wintersgill, J. P. Calame, and S. G. Greenbaum 1 May 1994 14 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A279271; TR-6) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Electrical conductivity/dielectric relaxation studies of acid form Nafion-117 have been carried out at frequencies from 10 to 10(exp 8) Hz. By direct measurement, it is shown that when standard two terminal measurements are made across the thickness of a 0.18 mm film, it is necessary to use frequencies in excess of 10(exp 7) Hz in order to observe the bulk conductivity of the sample. As a consequence, previous reports of a power law dependence for the electrical conductivity are not associated with the bulk electrical conductivity but rather are due to electrode effects and space charge. As confirmation, it is shown that by changing the geometry of the electrodes, the low frequency electrical response of the material is significantly changed. DTIC

(Contract DE-AC05-84OR-21400)
(DE94-019112; CONF-9405199-2) Avail: CASI HC A03/MF A01

Electronics developed for signal processing, digitization, and readout of a 10,000-element lead-glass electromagnetic calorimeter for CERN experiment WA98 are described. Chief among the components developed are two CMOS monolithic circuits. One, known as the 'Preamp' chip, includes eight channels each of integrator, dual gain amplifier, fast shaping amplifier, constant fraction discriminator, and also two 2 by 2 current sums for trigger purposes, and maskable calibration pulsers for the time and energy channels. It also includes three 6-bit DAC's for setting thresholds and calibration values. The other chip, known as the 'ATA' (AMU/TAC/ADC) chip, includes 16 channels of AMU (analog memory unit), 8 channels of TAC, and 24 channels of Wilkinson-type ADC. A description of these chips' design and performance is given, together with a short description of supporting circuitry and of initial system performance as measured with 2- to 20-GeV electrons. NON-LINEAR A/D CONVERTERS FOR INTEGRATED SILICON SMART SENSORS Ph.D. Thesis [NIET-LINEAIRE A/D OMZETTERS VOOR SMART GEIENTEGREERDE SILICIUM SENSOREN]
K. E. M. Mahmoud 26 Apr. 1994 37 p
(PB94-208402; ISBN-90-6275-976-9) Avail: Issuing Activity (National Technical Information Service (NTIS))

Many sensors have a wide dynamic range and a limited accuracy. The use of a high-resolution A/D converter to cover the sensor dynamic range adds to the cost of the system without any benefit being derived from the high resolution in respect to the system overall accuracy. A nonlinear A/D converter offers an optimal solution for digitizing the output of these sensors. The aim of this research was to develop a non-linear A/D converter that features a wide dynamic range (about 10(exp 15)) and a resolution of about 8 bits. Further, in this research, the effect of the post-processing annealing and the epilayer thickness and doping concentrations on the DC bipolar characteristics were investigated. DTIC

Electrohydrodynamic (EHD) flows are driven by the interaction of an electric field with variations in electric conductivity or dielectric constant. In reported EHD experiments on the deformation of drops of immiscible dielectric fluids, the role of conductivity has tended to overshadow the role of dielectric constant. Often, large conductivity contrasts were convenient because the conductivities of the dielectric fluid were relatively uncertain. As a result, the observed effects were always qualitatively the same as if there had been no contrast in dielectric constant. Our early experiments studying the EHC deformations of cylindrical streams readily showed the conductivity effect but the dielectric constant effect was not discernible. We have modified our flow chamber and improved our method of observation and can now see an unequivocal dielectric constant effect which is in agreement with the prior theory. In this paper we first give a brief description of the physics of charge buildup at the interface of an immersed spherical drop or flowing cylindrical sample stream and then show how these charge distributions lead to interface distortions and accompanying viscous flows which constitute EHD. We next review theory and experiment describing the deformation of spherical drops. We show that in the reported drop deformation experiments, the contrast in dielectric constant was never sufficient to reverse the deformation due to the conductivity contrast. We review our work describing the deformation of a cylindrical stream of one fluid flowing in a parallel flow of another, and we compare the deformation equations with those for spherical drops. Finally, we show a definite experimental dielectric constant effect for cylindrical stream of aqueous polystyrene latex suspension. The dielectric constant varies with the frequency of the imposed electric field, and the associated EHD flow change is very apparent. Author

InTlSb FOR LONG-WAVELENGTH INFRARED PHOTODETECTORS AND ARRAYS Annual Report

Manijeh Razeghi 1993 24 p
(Contract N00014-93-1-0409)
(AD-A280109) Avail: CASI HC A03/MF A01

The heteorepitaxial narrow-gap semiconductors on Si or GaAs substrates offer the possibility of monolithic integration of detectors and readout circuits in the infrared focal plane arrays (IRFPA's). This structure can avoid the problems of a complicated etch-thinning process and indium bump displace in the hybrid case. This structure permits the production of a large-area FPA's with high reliability and low cost. The purpose of this project is to develop III-V IRFPA on InSb, GaAs, Si substrates, special detectors made from In(1-x)Tl(x)Sb material system. The devices are of potential in the long wavelength (8-14 micrometers), particularly in the application of thermal imaging, as MCT materials suffer from poor composition uniform over large areas and thermal stability. As a preliminary step towards InTlSb photovoltaic detectors, it is necessary to establish a reliable procedure to fabricate InSb photovoltaic detectors. DTIC

AN 8-METER-LONG COUPLED CAVITY RFQ LINAC

L. M. Young 1994 4 p Presented at the 17th International LINAC Conference, Tsukuba, Japan, 21-26 Aug. 1994
(Contract W-7405-eng-36)
(DE94-018077; LA-UR-94-2686; CONF-9408125-8) Avail: CASI HC A01/MF A01

A model has been constructed of an 8-m-long high energy (7 MeV) Radio-Frequency Quadrupole (RFQ) to prove the concept of a resonantly coupled RFQ. The model consists of four 2-in-long RFQ segments resonantly coupled together. A small gap (3 mm) between the vane tips, at the segment joints, provides capacitive coupling. This model is of a RFQ designed for a proposed Los Alamos Accelerator Performance Demonstration Facility (APDF). The RFQ, as designed, will operate cw at 350 kHz and accelerate a 100-mA beam of protons to 7 MeV. DOE

COAXIAL HYBRID WIGGLER Patent Application

Robert H. Jackson, inventor, Henry P. Freund, inventor, Dean E. Pershing, inventor, and Jose M. Taccetti, inventor 12 Jul. 1994 28 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-D016501; US-Patent-Appl-SN-274183) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

An electromagnetic wiggler is introduced having a cylindrical member, and a central member disposed axially within the cylindrical member, both of which are formed from alternating cylindrical sections of ferromagnetic and non-ferromagnetic material, each sequential pair of these sections being the length of the wiggler's period Lambda w. The sequence of sections between the inner and outer members is shifted Lambda w/2, so that ferromagnetic sections of the outer member are disposed radially opposite non-ferromagnetic sections of the inner member, and vice versa. The resultant radial magnetic flux density in the cylindrical gap between the members is larger and sharper than the flux density for the same wiggler without the central member, permitting higher radiated power output, at higher radiation frequencies, for the same energy of input electron beam. RF VACUUM MICROELECTRONICS BASED ON THIN FILM EDGE-EMITTER TECHNOLOGY Final Report, Sep. 1991 - Feb. 1994

Tayo Akinwande Apr. 1994 69 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract MDA972-91-C-0030; ARPA Order 8162)
(AD-A279539) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

We report the design, fabrication, and demonstration of thin-film-edge emitter vacuum diodes and transistors. The two-terminal device uses a thin-film-edge emitter as an electron source whose current density depends on the anode voltage. The three terminal device uses a thin-film-edge emitter as an electron source whose current density depends on the voltage applied to the extraction electrodes (gates). The emitted electrons are collected by the anode. All three electrodes (emitter, gate, and anode) are integrated on the same substrate. The devices have integrated on-chip resistors for bum-out prevention. The 3D microstructure was fabricated using IC and micromachining techniques. Contrasted with the usual vertical FEA structures, the particular vacuum transistor design invokes two dimensional vertical symmetry for the extraction electrodes (gate) using multi-layer thin film deposition techniques. The central thin-film-edge emitter is about 300 A thick and is surrounded by two gate electrodes, one above and one below. DTIC

HIGH TEMPERATURE SUPERCONDUCTING FILMS AND MULTILAYERS FOR ELECTRONICS Final Report, 21 Feb. 1991 - 20 Feb. 1994

John R. Gavaler and John Talvacchio 19 Apr. 1994 209 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract F49620-91-C-0034)
(AD-A279545; WCTC-94-9SL2-Super-R1; AFOSR-94-0307TR) Avail: CASI HC A10

The overall objective of this program was to develop a materials and fundamental device base for high-transition-temperature superconducting (HTS) electronics capable of operating at greater than 50K. Progress is reported on four tasks which address problems fundamental to the understanding of the superconducting state in HTS films, the application of HTS films in passive microwave circuits, the realization of HTS digital electronics, and the development of new superconducting devices. Large-area epitaxial YBCO films with low RF losses developed under this program and techniques for depositing them on both sides of single-crystal substrates were used in other Westinghouse and government-funded programs to develop HTS channelized filterbanks, delay lines, UHF antenna matching networks, and low-phase-noise resonators. An understanding was achieved of the role of oxygenation during film growth and the effect of film microstructure on RF losses. For HTS digital circuit fabrication, both active devices step-edge and edge-type YBCO Josephson junctions and trilayer BKBO junctions and passive structures were developed, such as crossovers, vias, and contacts. These capabilities were transfered to other Westinghouse and government-funded programs which demonstrated the first HTS SFQ circuits and SQUID's with integrated ground planes. DTIC

CURRENT DISTRIBUTION IN CABLE-IN-CONDUIT CONDUCTORS M.S. Thesis
M. A. Ferri May 1994 104 p Prepared for Oak Ridge Inst. for Science and Education, TN
(Contracts DE-FC02-93ER-54186; DE-AC05-76OR-00033)
(DE95-001820; DOE/ER-54186/T5; PFC/RR-94-6) Avail: CASI HC A06/MF A02

A numerical study of the current distribution in Cable-In-Conduit Conductors (CICC's) experiencing linearly ramping transport currents and transverse magnetic fields was conducted for both infinitely long, periodic cables and finite length cables terminated in low resistance joints. The goal of the study was to gain insight into the phenomenon known as Ramp Rate Limitation, an as yet unexplained correspondence between maximum attainable current and the ramp time taken to reach that current in CICC superconducting magnets. A discrete geometric model of a 27 strand multiply twisted CICC was developed to effectively represent the flux linkages, mutual inductances, and resistive contact points between the strands of an experimentally tested cable. The results of the numerical study showed that for fully periodic cables, the current imbalances due to ramping magnetic fields and ramping transport currents are negligible in the range of experimentally explored operating conditions. For finite length, joint terminated cables, however, significant imbalances can exist. Unfortunately, quantitative results are limited by a lack of knowledge of the transverse resistance between strands in the joints. Nonetheless, general results are presented showing the dependency of the imbalance on cable length, ramp time, and joint resistance for both ramping transverse magnet fields and ramping transport currents. At the conclusion of the study, it is suggested that calculated current imbalances in a finite length cable could cause certain strands to prematurely 'quench' - become non-superconducting - thus leading to an instability for the entire cable. This numerically predicted 'current imbalance instability' is compared to the experimentally observed Ramp Rate Limitation for the 27 strand CICC sample. DOE

ELECTRIC AND HYBRID VEHICLE PROGRAM: SITE OPERATOR PROGRAM Quarterly Progress Report, Oct. - Dec. 1993
D. M. Kiser and J. F. Warren Mar. 1994 54 p
(Contract DE-AC07-76ID-01570)
(DE95-001925; EGG-EP-11237-Qtr1) Avail: CASI HC A04/MF A01

The DOE Site Operator Program was initially established to meet the requirements of the Electric and Hybrid Vehicle Research, Development, and Demonstration Act of 1976. The Program has since evolved in response to new legislation and interests. Its mission now includes three major activity categories: (1) Advancement of Electric Vehicle (EV) technologies; (2) development of infrastructure elements needed to support significant EV use; (3) increasing public awareness and acceptance of EV's. The 14 Program participants, their geographic locations, and the principal thrusts of their efforts are identified. The EV inventories of each participant are summarized. The topics of this report include participants' experience with EV operation; an appraisal of the overall current status of EV's for transportation; program management; and a program experience overview, the result of analyzing Site Operator inputs, provides an insight into the variables that can affect electric vehicle performance and operating cost. A number of samples have been grown in the Intervac-EPI solid-source Molecular Beam Epitaxy (MBE) system since it was first commissioned in early May, 1994. The samples have consisted of both undoped and doped InSb, undoped InAs and various calibration layers such as n-type and p-type GaAs doping staircases. The different surface reconstructions and surfaces phase transitions have been investigated using Reflection High Energy Electron Diffraction (RHEED). For example, InSb growth temperature is set relative to a c(4x4) to a(1x3) surface phase transition, corresponding to an actual surface temperature of 390 C. RHEED oscillations were observed for GaAs, InAs and InSb as this is particularly important for determining growth rates and III/V flux radio. The philosophy has been to determine system independent growth parameters so that the technology can be easily transferred to other growth systems. DTIC

MULTI-PORT TESTER INTERFACE Patent Application
Alvin Botelho, inventor (to Navy) 10 Feb. 1994 19 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-D016240; US-Patent-Appl-SN-194600) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

A multi-port tester interface is coupled between an interface port tester having only one test port and a plurality of interface ports to be tested. The multi-port tester interface includes timing and control logic which provides an initialization signal to the interface port tester. The timing and control logic controls an interface port selector to provide an interface port address to a test signal multiplexer and an input multiplexer. A test signal from the interface port tester is transmitted to the appropriate interface port under test through the test signal multiplexer. A successful test completion signal is received by the appropriate input of the test completion multiplexer as selected by the address provided by the interface port selector, and provided to an input port of the interface port tester. Each interface port to be tested is thus sequentially yet automatically coupled to the interface port tester, and is sequentially tested without

connecting and disconnecting individual interface ports from a tester. Appropriate reset and voltage level signal shifting circuitry is also provided.

MONOLITHIC LOW NOISE PREAMPLIFIER FOR PIEZOELECTRIC SENSORS Patent
Timothy B. Straw, inventor (to Navy) 16 Aug. 1994 6 p Filed 12 Apr. 1993
(AD-D016524; US-Patent-5,339,285; US-Patent-Appl-SN-045143; US-Patent-Class-367-135) Avail: US Patent and Trademark Office

A preamplifier for a piezoelectric sensor requiring a high-impedance, low noise interface circuit is introduced. The preamplifier is a single, monolithic integrated circuit that can be mounted directly onto or inside a miniature sensor without degrading the sensor's performance. The preamplifier performs signal amplification with a full-differential amplifier that includes common-mode feedback. A pair of feedback capacitors together with the sensor capacitance control the voltage gain of the preamplifier over much of it's useful operating range of 100 Hz to 100 kHz. The preamplifier circuit also has feedback resistors that discharge any accumulated DC voltage which might appear on the capacitors. Also the feedback resistors form a high pass filter which rejects low frequency background noise from the sensor. DTIC

INTEGRATION OF THIN FILM DECOUPLING CAPACITORS
Terry Garino, Duane Dimos, and Steve Lockwood 1994 6 p Presented at the Meeting on the Revolution in Microelectronics, Boston, MA, 15-17 Nov. 1994
(Contract DE-AC04-94AL-85000)
(DE95-001609; SAND-94-2239C; CONF-941199-2) Avail: CASI HC A02/MF A01

Thin film decoupling capacitors consisting of submicron thick, sol-gel Pb(Zr,Ti)O3 layers between Pt electrodes on a Si substrate have recently been developed. Because the capacitor structure needs to be only (approximately) 3 micrometers thick, these devices offer advantages such as decreased package volume and ability to integrate so that interconnect inductance is decreased, which allows faster IC processing rates. To fully utilize these devices, techniques of integrating them onto packages such as multi-chip modules and printed wiring boards or onto IC dies must be developed. The results of our efforts at developing integration processes for these capacitors are described here. Specifically, we have demonstrated a process for printing solder on the devices at the Si wafer level and reflowing it to form bumps and have developed a process for fabricating the devices on thin (25 to 75 micrometers) substrates to facilitate integration onto IC's and printed wiring boards. Finally, we assessed the feasibility of fabricating the devices on rough surfaces to determine whether it would be possible to fabricate these capacitors directly on multi-layer ceramic substrates. MAGNETOSTRICTIVE MOTOR SYSTEM Patent
Bruce S. Maccabee, inventor (to Navy) 23 Aug. 1994 7 p Filed 18 Jan. 1991
(AD-D016484; US-Patent-5,341,056; US-Patent-Appl-SN-643632; US-Patent-Class-310-26) Avail: US Patent and Trademark Office

A plurality of drive modules positioned at spaced locations along a drive path of a driven member respectively include two magnetostrictive rod elements in alignment with each other, with adjacent ends thereof in engagement with a third magnetostrictive rod element extending transversely of the drive path to engage the driven member. Simultaneous elongation and contraction of the two rod elements during elongation of the third rod element in the drive modules imparts unidirectional motion to the driven member. DTIC

N95-21906 Department of the Navy, Washington, DC.
THORIATED-TUNGSTEN, SPLIT-RING, HOLLOW-CATHODE ELECTRODE FOR DISCHARGE DEVICES Patent
Edward J. Seibert, inventor (to Navy), Gerald D. Ferguson, inventor (to Navy), and Marie E. Taylor, inventor (to Navy) 27 Sep. 1994 7 p Filed 14 Mar. 1994
(AD-D016508; US-Patent-5,351,260; US-Patent-Appl-SN-209345; US-Patent-Class-372-84) Avail: US Patent and Trademark Office

An electrode assembly for a gas or metal vapor discharge device is disclosed. A pair of electrode assemblies each comprising thoriated tungsten with an alloy composition of tungsten (W) and from about 2% to about 3% of thorium dioxide, ThO2, are located at opposite ends of the discharge chamber of the discharge device. The tip of the electrode preferably has four slots equally spaced around its circumference and a groove at its outermost edge. The tip of the electrode provides mechanical flexibility that inhibits the cracking of the thoriated tungsten electrode when it is mounted in the discharge device. Each electrode assembly further comprises a copper spacer, preferably I-shaped in cross-section, brazed against the base of the electrode and against a vacuum flange. The pair of electrode assemblies confines the discharge of the discharge device between the tips of the electrodes and inhibits the arc condition from finding its way to delicate vacuum seals. DTIC

GROWTH AND ELECTRICAL AND FAR-INFRARED PROPERTIES OF WIDE ELECTRON WELLS IN SEMICONDUCTORS Final Technical Report, 15 Feb. 1991 - 14 Feb. 1994
Arthur C. Gossard 15 Apr. 1994 122 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Grant AF-AFOSR-0214-91)
(AD-A279409; UCSB-08-075892; AFOSR-94-0285TR) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The thrust of the research carried out under this grant has been the development and study of wide, specially shaped graded quantum wells for electrons in semiconductors, as synthesized by high-precision epitaxial growth. In basic characterization of the wide wells, fundamental measurements of charge density, energy levels, and electron motions in the wells were pursued. The achievement of high-Q solid state electron resonators at Terahertz frequencies in the wide wells was stressed. Highly resonant cavities with electron scattering times nearly two orders of magnitude larger than for electrons in high-purity uniformly doped wells of comparable electron concentration have been grown. Structures were also achieved in which the resonant frequency of the electrons could be changed by application of a potential to a control electrode. Modification of the parabolic potential by superposition of periodic potentials and the extension of the parabolic well concept to remotely doped hole wells were also emphasized. DTIC

ELECTRIC AND HYBRID VEHICLE PROGRAM SITE OPERATOR PROGRAM
D. M. Kiser and J. F. Warren Aug. 1994 54 p
(Contract DE-AC07-76ID-01570)
(DE95-002042; EGG-EP-11237-Qtr2) Avail: CASI HC A04/MF A01

The Site Operator Program was initially established by the Department of Energy (DOE) to incorporate the electric vehicle activities dictated by the Electric and Hybrid Vehicle Research, Development and Demonstration Act of 1976. The Program currently includes thirteen sites located in diverse geographic, metrological,and metropolitan areas across the United States. Information is shared reciprocally with a fourteenth site, not under Program contract. The vehicles are operator-owned, except for two Griffon vans. The Mission Statement of the Site Operator Program includes three major activities: (1) Advancement of electric vehicle technologies. (2) Development

of infrastructure elements necessary to support significant electric vehicle use; and (3) Increasing the awareness and acceptance of electric vehicles (EVs) by the public. The ultimate thrust of program activities varies among sites, reflecting not only the Operator's business interests but also geographic and climate-related operating conditions. These considerations are identified below for each Program Status entry. This second quarter report (FY-94) will include a summary of activities from the previous three quarters.

A 500 MW ANNULAR BEAM RELATIVISTIC KLYSTRON
M. V. Fazio, W. B. Haynes, B. E. Carlsten, and R. M. Stringfield 1994 4 p Presented at the 17th International LINAC Conference, Tsukuba, Japan, 21-26 Aug. 1994
(Contract W-7405-eng-36)
(DE95-000867; LA-UR-94-3101; CONF-9408125-34) Avail: CASI HC A01/MF A01

This paper describes the experimental development of a long pulse, high current, annular beam relativistic klystron amplifier. The desired performance parameters are 1 GW output power and 1 (mu)s pulse length with an operating frequency of 1.3 GHz. The electron beam voltage and current are nominally 600 kV and 5 kA. Peak powers approaching 500 MW have been achieved in pulses of 1 (mu)s nominal baseline-to-baseline duration. The half power pulse width is 0.5 (mu)s. These pulses contain an energy of about 160 J. The design of this class of tube presents some unique challenges, particularly in the output cavity. The output cavity must exhibit a very low gap shunt impedance in order to obtain reasonable conversion efficiency from the low impedance modulated electron beam to microwave power, while still maintaining a reasonable loaded Q for mode purity. The physics of this device is dominated by space charge effects which strongly impact the design. Current experimental results and theoretical design considerations for this class of tube, and scaling to higher frequency operation, suitable for the Next Linear Collider are discussed.

UNINTERRUPTED, ENHANCED-RATE EVENT SEQUENCER WITH MIXED-SPEED COUNTER MODULES Patent
Willard M. Cronyn, inventor (to Navy) 5 Apr. 1994 9 p Filed 18 Dec. 1991
(AD-D016255; US-Patent-5,301,219; US-Patent-Appl-SN-809349; US-Patent-Class-377-44) Avail: US Patent and Trademark Office

The invention includes a data memory having sequentially stored N-bit words that are each a binary description of a time at which an event is to occur. Also stored is a K-bit word, associated with each N-bit word, that is a binary description of what the scheduled event is to be. The invention utilizes a free-running clock and clock circuitry to gauge when an event should occur. The clock circuitry tallies an N-bit description of running time. M-bits of the N-bit description of running time are specified by a single fast synchronous counter. The remaining N-M bits are specified by two slow counters each of N-M bit capacity. Because incrementation of slow counters creates count settling times that may significantly affect accurate event sequencing, the slow counters are alternately incremented and a multiplexer is used to switch to the counter that will provide a 'steady state' count at a scheduled event time.

SEU AND SEL RESPONSE OF THE WESTINGHOUSE 64K E-2PROM, ANALOG DEVICES AD7876 12-BIT ADC, AND THE INTEL 82527 SERIAL COMMUNICATIONS CONTROLLER
F. W. Sexton, G. L. Hash, M. P. Connors, J. R. Murray, J. R. Schwank, P. S. Winokur, and E. G. Bradley 1994 9 p Presented at the 31st Annual International Nuclear and Space Radiation Effects Conference, Tucson, AZ, 18-22 Jul. 1994
(Contract DE-AC04-94AL-85000)
(DE95-003349; SAND-94-0449C; CONF-940726-16) Avail: CASI HC A02/MF A01

The Westinghouse SA3823 64K E(sup 2)PROM radiation-hardened SONOS non-volatile memory exhibited a single-event-upset (SEU) threshold in the read mode of 60 MeV-sq cm/mg and 40 MeV-sq cm/mg for data latch errors. The minimum threshold for address latch errors was 35 MeV-sq cm/mg. Hard errors were observed with Kr at V(sub p) = 8.5 V and with Xe at Programming voltages (V(sub p)) as low as 7.5 V. No hard errors were observed with Cu at any angle up to V(sub p) = II V. The system specification of no hard errors for Ar ions or lighter was exceeded. No single-event latchup (SEL) was observed in these devices for the conditions examined. The Analog Devices AD7876 12bit analog-to-digital converter (ADC) had an upset threshold of 2 MeV-cm(sup 2)/mg for all values of input voltage (V(sub in)), while the worst-case saturation cross section of approximately 2 x 10(exp -3)sq cm as measured with V(sub in) = 4.49 V. No latchup was observed. The Intel 82C527 serial communications controller exhibited a minimum threshold for upset of 2 MeV-cm(exp 4)/mLi, and a saturation cross section of about 5 x 10(exp-4)sq cm. For latchup the minimum threshold was measured at 17 MeV-sq cm/mg, and cross section saturated at about 3 x10(exp -4)sq cm. Error rates for the expected applications are presented.

PERFORMANCE OF Ga(0.47)In(0.53)As CELLS OVER A RANGE OF PROTON ENERGIES
I. Weinberg, R. K. Jain (Toledo Univ., OH.), C. VargasAburto (Kent State Univ., OH.), D. M. Wilt, and D. A. Scheiman (NYMA, Inc., Brook Park, OH.) Jan. 1995 6 p Presented at the First World Conference on Photovoltaic Energy Conversion, Waikoloa, HI, 5-9 Dec. 1994; sponsored by IEEE, PVSEC-Japan and PSEC-Europe
(Contract NAS3-27186; RTOP 233-02-0A)
(NASA-TM-106819; E-9359; NAS 1.15:106819) Avail: CASI HC A02/MF A01

Ga(0.47)In(0.53)As solar cells were processed by OMVPE and their characteristics determined at proton energies of 0.2, 0.5, and 3 MeV. Emphasis was on characteristics applicable to use of this cell as the low bandgap member of a monolithic, two terminal high efficiency InP/GaInAs cell. It was found that the radiation induced degradation in efficiency, I(sub SC), V(sub OC) and diffusion length increased with decreasing proton energy. When efficiency degradations were compared with InP it was observed that the present cells showed considerably more degradation over the entire energy range. Similar to InP, R(sub C), the carrier removal rate, decreased with increasing proton energy. However, numerical values for R(sub C) differed from those observed with InP. The difference is attributed to differing defect behavior between the two cell types. It was concluded that particular attention should be paid to the effects of low energy protons especially when the particle's track ends in one cell of the multibandgap device.

DEFECT CLASSES: AN OVERDUE PARADIGM FOR CMOS IC TESTING

C. F. Hawkins (New Mexico Univ., Albuquerque, NM.), J. M. Soden, A. W. Righter, and F. J. Ferguson (California Univ., Santa Cruz, CA.) 1994 13 p Presented at the International Test Conference, Washington, DC, 3-5 Oct. 1994
(Contract DE-AC04-94AL-85000)
(DE94-018905; SAND-94-2009C; CONF-9410194-1) Avail: CASI HC A03/MF A01

The IC test industry has struggled for more than 30 years to establish a test approach that would guarantee a low defect level to the customer. We propose a comprehensive strategy for testing CMOS IC's that uses defect classes based on measured defect electrical properties. Defect classes differ from traditional fault models. Our defect class approach requires that the test strategy match the defect electrical properties, while fault models require that IC defects match the fault definition. We use data from Sandia Labs failure analysis and test facilities and from public literature. We describe test pattern requirements for each defect class and propose a test paradigm. DOE

SUB-MILLIMETERWAVE SEMICONDUCTOR SIGNAL SOURCES Final Report, Aug. 1990 - Aug. 1993
S. E. Rosenbaum Apr. 1994 38 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract F19628-90-C-0171)
(AD-A279375; HAC-REF-J1881; RL-TR-94-13) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Research on Indium Phosphide Pseudomorphic High Electron Mobility Transistors (InP PHEMT's) resulted in 155 GHz and 215 GHz monolithic integrated circuit oscillators. These circuits represent the highest frequencies achieved to date for a fundamental signal source using a three terminal device. Advances in epitaxial growth of the pseudomorphic semiconductor structures and the achievement of low-resistance, 50-nm-long self-aligned gates resulted in the highest short circuit current gain cutoff frequency (ft) transistors ever reported. The planar quasi-optical slot oscillators verify the high frequency capabilities of the InP PHEMT. Hughes Laboratories performed the research on materials, device design and processing device characterization and modeling. The University of Michigan designed the oscillator circuits, including the integrated planar antennas, and measured the, oscillator performance. DTIC

PLASMA PROCESSING FOR INTEGRATED CIRCUITS
L. A. Berry 1994 7 p Presented at the 1993 Fusion Power Associates Annual Meeting, Oak Ridge, TN, 4-6 Oct. 1993
(Contract DE-AC05-84OR-21400)
(DE95-001419; CONF-9310209-2) Avail: CASI HC A02/MF A01

The steady advance of integrated circuit technology is one of the most remarkable technology trends in this era of technological revolution. For example, the 64-k memory chips of the early 1980s are now being replaced by 4-M and even 16-M chips. This trend is expected to continue with chips at the giga-bit level being available in a decade. The needs for ultraviolet and then X-ray lithography to define the submicron features needed for these larger, denser chips have been widely discussed. However, in parallel, the equipment (referred to as tools in the industry) and related processes to carry out the deposition and etching steps needed to actually produce devices in the tenth-micron range also require significant development. This paper summarizes present and anticipated contributions of magnetic fusion plasma theory and diagnostics and plasma production technology at Oak Ridge National Laboratory (ORNL) for the development of integrated circuit production technology. The discussion is introduced with a review of past technology evolution and of the present economic context for manufacturing. DOE

RADIATION CHARACTERIZATION REPORT FOR THE GPS RECEIVER MICROCONTROLLER CHIP
20 Jun. 1994 16 p Prepared in cooperation with Novus Technologies, Inc., Albuquerque, NM
(Contract W-7405-eng-36)
(DE94-019169; LA-SUB-94-122) Avail: CASI HC A03/MF A01

The overall objective of this characterization test was to determine the sensitivity of the Motorola 68332 32-bit microcontroller to radiation induced single event upset and latch-up (SEU/SEL). The microcontroller is a key component of the GPS Receiver which will be a subsystem of the satellite required for the 'FORTE' experiment. Testing was conducted at the Single Event Effects Laboratory at Brookhaven National Laboratory. The results obtained included a latch-up (SEL) threshold LET (Linear Energy Transfer) of 20 MeV-sq cm/mg and an upset (SEU) threshold LET of 5 MeV-sq cm/mg. The SEU threshold is typical of this technology, commercial 0.8 micrometers HCMOS. Some flow errors were observed that were not reset by the internal watchdog timer of the 68332. It is important that the Receiver design include a monitor of the device, such as an external watch-dog timer, that would initiate a reset of the program when this type of upset occurs. The SEL threshold is lower than would be expected for this 12 micrometer epi layer process and suggests the need for a strategy that would allow for a hard reset of the controller when a latch-up event occurs. Analysis of the galactic cosmic ray spectrum for the FORTE orbit was done and the results indicate a worst case latch-up rate for this device of 6.3 x 10(exp -5) latch-ups per device day or roughly one latch-up per 43.5 device years. RADIATION TESTS ON SERVICE ELECTRONICS FOR FUTURE MULTI TeV DETECTORS
H. Larsen, H. Schoenbacher, T. Massam (Istituto Nazionale di Fisica Nucleare, Bologna, Italy.), and F. Wulf (Hahn-Meitner-Inst. G.m.b.H., Berlin, Germany.) 12 Oct. 1993 107 p
(DE94-632822; CERN-93-04) Avail: CASI HC A06/MF A02 (US Sales Only)

Irradiation tests of a number of essential components for use in the service electronics of the Leading Proton Spectrometer (LPS) have been undertaken. The components are simple medium-scale integrated circuits such as Transistor Transistor Logic (TTL) buffers from the Advanced Low-power Schottky (ALS), Low-power Schottky (LS), and Fast (F) families, optocouplers, and balanced line drivers and receivers. More complex circuits, such as a Fuse Programmable Array Logic chip, programmed as a 6-bit counter, and a complete switched-mode power supply unit were also tested. Further, monolithic voltage regulators with an output potential of 5 V, and 10 MHz quartz oscillator hybrids were tested. The different radiation fields were X-rays (80 keV), (sup 60)Co gamma rays, electrons (2.5 MeV), and a high-energy proton accelerator environment. Depending on the device degradation, the maximum dose was up to 0.8 MGy. It is shown that the simple choice of circuit family can achieve a hardness level of nearly 1 MGy(Si), provided that one is prepared to make some sacrifices in power consumption, and in speed. It has been found that this radiation hardness can be reached with LS technology. The maximum level of about 1 MGy(Si) was obtained with 2.5 MeV electrons, which is equivalent to a 1 MeV neutron fluence of the order of 6x10(exp 13)/sq cm. DOE

ESTIMATION OF LIGHTNING STROKE PEAK CURRENT AS A FUNCTION OF PEAK ELECTRIC FIELD AND THE NORMALIZED AMPLITUDE OF SIGNAL STRENGTH: CORRECTIONS AND IMPROVEMENTS
Y. P. Liaw, D. R. Cook, and D. L. Sisterson 1994 18 p
(Contract W-31-109-eng-38)
(DE94-016900; ANL/ER/PP-82416) Avail: CASI HC A03/MF A01

Corrections and improvements have been made to published equations relating return stroke peak current and peak electric field for cloud-to-ground lightning. The original equations were derived from measurements made at the Rocket-Triggered-Lightning Program (RTLP) facility at the Kennedy Space Center in Florida. Some previous articles include errors in the conversion of equations from units of volts per meter, for peak electric field, into lightning location and protection units, representing normalized signal strength amplitude. This article presents the proper conversion procedure and the resultant corrected equations. Furthermore, equations are presented that were produced by converting other published relationships. Finally, we combined 1985-1988 RTLP data to produce equations based on more data than has been used previously; the resulting equation for peak current as a function of normalized signal strength amplitude supports previous evidence that the slope should be near 0.2 for a zero intercept. All relationships are tabulated, and three are graphically compared against the data. DOE

REFLECTIVE MASKS FOR EXTREME ULTRAVIOLET LITHOGRAPHY Ph.D. Thesis
Khanh Bao Nguyen May 1994 146 p
(Contract DE-AC03-76SF-00098)
(DE95-003427; LBL-36078) Avail: CASI HC A07/MF A02

Extreme ultraviolet lithographic masks are made by patterning multilayer reflective coatings with high normal incidence reflectivity. Masks can be patterned by depositing a patterned absorber layer above the coating or by etching the pattern directly into the coating itself. Electromagnetic simulations showed that absorber-overlayer masks have superior imaging characteristics over etched masks (less sensitive to incident angles and pattern profiles). In an EUVL absorber overlayer mask, defects can occur in the mask substrate, reflective coating, and absorber pattern. Electromagnetic simulations showed that substrate defects cause the most severe image degradation. A printability study of substrate defects for absorber overlayer masks showed that printability of 25 nm high substrate defects are comparable to defects in optical lithography. Simulations also indicated that the manner in which the defects are covered by multilayer reflective coatings can affect printability. Coverage profiles that result in large lateral spreading of defect geometries amplify the printability of the defects by increasing their effective sizes. Coverage profiles of Mo/Si coatings deposited above defects were studied by atomic force microscopy and TEM. Results showed that lateral spread of defect geometry is proportional to height. Undercut at defect also increases the lateral spread. Reductions in defect heights were observed for 0.15 micro m wide defect lines. A long-term study of Mo/Si coating reflectivity revealed that Mo/Si coatings with Mo as the top layer suffer significant reductions in reflectivity over time due to oxidation. DOE

DEVELOPMENT OF PRACTICAL HIGH TEMPERATURE SUPERCONDUCTING WIRE FOR ELECTRIC POWER APPLICATIONS
Robert A. Hawsey, Robert S. Sokolowski (Intermagnetics General Corp., Latham, NY.), Pradeep Haldar (Intermagnetics General Corp., Latham, NY.), and Leszek R. Motowidlo (IGC Advanced Superconductors, Inc., Waterbury, CT.) 1994 9 p Presented at the 4th International Conference and Exhibition of the World Congress on Superconductivity, Orlando, FL, 27 Jun. - 1 Jul. 1994
(Contracts DE-AC05-84OR-21400; DE-FG02-92ER-81461)
(DE94-017894; CONF-940627-4) Avail: CASI HC A02/MF A01

The technology of high temperature superconductivity has gone from beyond mere scientific curiosity into the manufacturing environment. Single lengths of multifilamentary wire are now produced that are over 200 meters long and that carry over 13 amperes at 77 K. Short-sample critical current densities approach 5 x 10(exp 4) A/sq cm at 77 K. Conductor requirements such as high critical current density in a magnetic field, strain-tolerant sheathing materials, and other engineering properties are addressed. A new process for fabricating round BSCCO-2212 wire has produced wires with critical current densities as high as 165,000 A/sq cm at 4.2 K and 53,000 A/sq cm at 40 K. This process eliminates the costly, multiple pressing and rolling steps that are commonly used to develop texture in the wires. New multifilamentary wires with strengthened sheathing materials have shown improved yield strengths up to a factor of five better than those made with pure silver. Many electric power devices require the wire to be formed into coils for production of strong magnetic fields. Requirements for coils and magnets for electric power applications are described. DOE

PARALLEL NANOMETER SCALE FABRICATION Final Report, 19 Sep. 1989 - 14 Sep. 1992
K. Douglas Sep. 1993 14 p
(Contract DE-FG02-89ER-14077)
(DE95-002122; DOE/ER-14077/T1) Avail: CASI HC A03/MF A01

Our approach to nanotechnology stresses parallel (as opposed to serial) processing and self-assembly techniques and we have demonstrated a basic parallel nanofabrication process that will enable a wide variety of nanometer-scale structures to be made. The process of nanometer molecular lithography employs two-dimensional biomolecular crystals as patterning elements in the parallel fabrication of structures on the 1-10 nm length scale. We have further demonstrated the fabrication of composite biomolecular/solid state heterostructures of nanometer dimension (nanoheterostructures). We are presently pursuing central issues in the development of nanotechnology such as the understanding and control of fluctuations and structural variations as well as applications of our nanofabrication process. An example of the latter is the formation of porous silicon having monodisperse arrays of silicon 'quantum wires' to elucidate the role of quantum confinement in the phenomenon of luminescent silicon. MULTI SIGNAL-DOMAIN MODELING OF SOLID-STATE TRANSDUCERS: A THEORETICAL FRAMEWORK BASED ON IRREVERSIBLE THERMODYNAMICS MIXED FINITE ELEMENTS AND MULTIGRID Ph.D. Thesis
Dave C. vanDuyn 29 Nov. 1993 263 p
(PB95-134995; ISBN-90-6275-932-7) Copyright Avail: Issuing Activity (National Technical Information Service (NTIS))

The more specific aims of this dissertation is the modeling and simulation of the thermoelectric effects in silicon solid-state transducers. This work is roughly split into two main parts. The first part (Chapters 2 and 3) deals with the construction of a physical model of the thermoelectric effects in the continuous space-time domain. The second part (Chapters 4, 5 and 6) deals with the implementation of the thermoelectric model. This work is, therefore, organized as follows: In Chapter 2, the authors discuss some generic aspects of physically based system models that can be used to model the (real-time) behavior of solid-state transducer configurations. In Chapter 3, a concrete example of the considerations presented in Chapter 2 is discussed, which is the modeling of the thermal and electrical energy domain for the case of a generic semiconductor. In Chapter 4, the authors discuss the transformation of the continuous space-time model into its discrete equivalent. In Chapter 5 the authors discuss a rather unconventional method for solving these discrete equations numerically. Chapter 6 deals with some of the practical implementation issues. Finally, in Chapter 7 the authors give illustrative examples. NTIS

The previous quarter saw attainment of the target 1g/hr diamond deposition at 75kW, as well as full power continuous operation of the AX6600 system. In this quarter we have focused on process chemistry at full power, exploring the operating range of the AX6600 and process chemistry variables. Specific process conditions we have explored include: deposition rates from 300 mg/hr to over 900 mg/hr, operation from 50 to over 75 kW, deposition on areas from 6 diameter to 12 diameter, deposition on a variety of substrate materials and techniques for intact release of the diamond at the end of the deposition step, deposition of non-uniform films for stress/flatness control. PRE-AMPLIFIER WITH MULTI-STAGE FEEDBACK Patent Application
James D. Hagerty, inventor (to Navy) 25 Mar. 1994 16 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-D016254; US-Patent-Appl-SN-215879) Avail: CASI HC A03

A circuit for amplifying an input signal comprises an operational amplifier, a dual operational amplifier, and a buffering operational amplifier all cascaded in the aforementioned order. The first operational amplifier amplifies the input signal with minimum noise degradation, is set up as a non-inverting amplifier stage, and has a local negative feedback loop comprising a resistor and capacitor in parallel. The dual operational amplifier has two amplifying devices. One device forms a second amplifying stage which increases the gain of the pre-amplified input signal and has a local negative feedback loop comprising a resistor. DTIC

DEMONSTRATION OF ZINC/AIR FUEL BATTERY TO ENHANCE THE RANGE AND MISSION OF FLEET ELECTRIC VEHICLES: PRELIMINARY RESULTS IN THE REFUELING OF A MULTICELL MODULE
J. F. Cooper, D. Fleming, L. Keene, A. Maimoni, K. Peterman, and R. Koopman Aug. 1994 9 p Presented at the 29th Intersociety Energy Conversion Engineering Conference, Monterey, CA, 7-12 Aug. 1994
(Contract W-7405-eng-48)
(DE95-004206; UCRL-JC-117946; CONF-940812-23) Avail: CASI HC A02/MF A01

We report progress in an effort to develop and demonstrate a refuelable zinc/air battery for fleet electric vehicle applications. A refuelable module consisting of twelve bipolar cells with internal flow system has been refueled at rates of nearly 4 cells per minute, indicating a refueling time of 10 minutes for a 15 kW, 55 kWh battery. The module is refueled by entrainment of 0.5-mm particles in rapidly flowing electrolyte, which delivers the particles into hoppers above each cell in a parallel-flow hydraulic circuit. The concept of user-recovery is presented as an alternative to centralized service infrastructure during market entry. DOE

UNIQUE MICROCHANNEL PLATE PROCESS DOUBLES MCPI RESOLUTION
S. Thomas and G. Power 22 Aug. 1994 7 p Presented at the 21st International Congress on High Speed Photography and Photonics, Taejon, Republic of Korea, 29 Aug. - 2 Sep. 1994
(Contract W-7405-eng-48)
(DE94-017507; UCRL-JC-116838; CONF-9408148-1) Avail: CASI HC A02/MF A01

Applying a dielectric layer to the output of a microchannel plate (MCP) has allowed the screen voltage of a sealed microchannel-plate intensifier tube (MCPI) to be raised to over 10 kV, producing a field strength of 36 kV/mm without any detectable field emission or breakdown of the MCP/screen gap. Tube resolution exceeded 16l p/mm at 50% modulation. Breakdown is higher in a dielectric than in a vacuum. In a concept being patented by Gary Power, a few micrometers thick layer of a dielectric was sputtered onto the output surface of an 18 mm MCP, which was incorporated into a tube under a contract for four tube starts. This process is applicable to any device incorporating a proximity-focused MCP and screen, including streak tubes and gated MCP x-ray imagers. Other improvements discussed include a patented use of a collimator for eliminating the electrons that are elastically scattered from the screen. This method also provides for further improvements in screen gap limited resolution to any desired degree by eliminating electrons with high transverse energy. This occurs at the expense of output brightness, which can be recovered through an appropriate increase in screen voltage. DOE

EXPERIMENTAL STUDY OF VANE HEAT TRANSFER AND AERODYNAMICS AT ELEVATED LEVELS OF TURBULENCE Final Report
Forrest E. Ames Cleveland, OH NASA Nov. 1994 125 p
(Contract NAS3-25950; RTOP 505-62-10)
(NASA-CR-4633; E-9203; NAS 1.26:4633) Avail: CASI HC A06/MF A02

A four vane subsonic cascade was used to investigate how free stream turbulence influences pressure surface heat transfer. A simulated combustor turbulence generator was built to generate high level (13 percent) large scale (Lu approximately 44 percent inlet span) turbulence. The mock combustor was also moved upstream to generate a moderate level (8.3 percent) of turbulence for comparison to smaller scale grid generated turbulence (7.8 percent). The high level combustor turbulence caused an average pressure surface heat transfer augmentation of 56 percent above the low turbulence baseline. The smaller scale grid turbulence produced the next greatest effect on heat transfer and demonstrated the importance of scale on heat transfer augmentation. In general, the heat transfer scaling parameter U(sub infinity) TU(sub infinity) LU(sub infinity)(exp -1/3) was found to hold for the turbulence. Heat transfer augmentation was also found to scale approximately on Re(sub ex)(exp 1/3) at constant turbulence conditions. Some evidence of turbulence intensification in terms of elevated dissipation rates was found along the pressure surface outside the boundary layer. However, based on the level of dissipation and the resulting heat transfer augmentation, the amplification of turbulence has only a moderate effect on pressure surface heat transfer. The flow field turbulence does drive turbulent production within the boundary layer which in turn causes the high levels of heat transfer augmentation. Unlike heat transfer, the flow field straining was found to have a significant effect on turbulence isotropy. On examination of the one dimensional spectra for u' and v', the effect to isotropy was largely limited to lower wavenumber spectra. The higher wavenumber spectra showed little or no change. The high level large scale turbulence was found to have a strong influence on wake development. The free stream turbulence significantly enhanced mixing resulting in broader and shallower wakes than the baseline case. High levels of flow field turbulence were found to correlate with a significant increase in total pressure loss in the core of the flow. Documenting the wake growth and characteristics provides boundary conditions for the downstream rotor. Author

LIQUID-METAL PIN-FIN PRESSURE DROP BY CORRELATION IN CROSS FLOW

Zhibi Wang, T. M. Kuzay, and L. Assoufid 1994 9 p Presented at the International Meeting on Synchrotron Radiation Instrumentation, Stony Brook, NY, 18-22 Jul. 1994
(Contract W-31-109-eng-38)
(DE94-017086; ANL/XFD/CP-82933; CONF-940714-16) Avail: CASI HC A02/MF A01

The pin-fin configuration is widely used as a heat transfer enhancement method in high-heat-flux applications. Recently, the pin-fin design with liquid-metal coolant was also applied to synchrotron-radiation beamline devices. This paper investigates the pressure drop in a pin-post design beamline mirror with liquid gallium as the coolant. Because the pin-post configuration is a relatively new concept, information in literature about pin-post mirrors or crystals is rare, and information about the pressure drop in pin-post mirrors with liquid metal as the coolant is even more sparse. Due to this the authors considered the cross flow in cylinder-array geometry, which is very similar to that of the pin-post, to examine the pressure drop correlation with liquid metals over pin fins. The cross flow of fluid with various fluid characteristics or properties through a tube bank was studied so that the results can be scaled to the pin-fin geometry with liquid metal as the coolant. Study led to two major variables to influence the pressure drop: fluid properties, viscosity and density, and the relative length of the posts. Correlation of the pressure drop between long and short posts and the prediction of the pressure drop of liquid metal in the pin-post mirror and comparison with an existing experiment are addressed. AUGMENTED THERMAL BUS Patent Application

Dean S. Schrage, inventor (to NASA) (Aerospace Design and Fabrication, Inc., Brook Park, OH.) 25 Jun. 1993 24 p
(NASA-Case-LEW-15595-1-C; NAS 1.71:LEW-15595-1-C; US-Patent-Appl-SN-081891) Avail: CASI HC A03/MF A01

The present invention is directed to an augmented thermal bus. In the present design a plurity of thermo-electric heat pumps are used to couple a source plate to a sink plate. Each heat pump is individually controlled by a model based controller. The controller coordinates the heat pump to maintain isothermality in the source. NASA

EFFECT OF MICROGRAVITY ON MATERIAL UNDERGOING MELTING AND FREEZING: THE TES EXPERIMENT

David Namkoong, David Jacqmin, and Andrew Szaniszlo Jan. 1995 12 p Presented at the 33rd Aerospace Sciences Meeting and Exhibit, Reno, NV, 9-12 Jan. 1995; sponsored byAIAA
(RTOP 233-03-0B)
(NASA-TM-106845; E-9414; NAS 1.15:106845; AIAA Paper 95-0614)
Avail: CASI HC A03/MF A01

This experiment is the first to melt and freeze a high temperature thermal energy storage (TES) material under an extended duration of microgravity. It is one of a series to validate an analytical computer program that predicts void behavior of substances undergoing phase change under microgravity. Two flight experiments were launched in STS-62. The first, TES-1, containing lithium fluoride in an annular volume, performed flawlessly in the 22 hours of its operation. Results are reported in this paper. A software failure in TES-2 caused its shutdown after 4 seconds. A computer program, TESSIM, for thermal energy storage simulation is being developed to analyze the phenomena occurring within the TES containment vessel. The first order effects, particularly the surface tension forces, have been incorporated into TESSIM. TESSIM validation is based on two types of results. First is the temperature history of various points of the containment structure, and second, upon return from flight, the distribution of the TES material within the containment vessel following the last freeze cycle. The temperature data over the four cycles showed a repetition of results over the third and fourth cycles. This result is a confirmation that any initial conditions prior to the first cycle had been damped out by the third cycle. The TESSIM simulation showed a close comparison with the flight data. The solidified TES material distribution within the containment vessel was obtained by a tomography imaging process. The frozen material was concentrated toward the colder end of the annular volume. The TESSIM prediction showed the same pattern. With the general agreement of TESSIM and the data, a computerized visual representation can be shown which accurately shows the movement and behavior of the void during the entire freezing and melting cycles. FLOW COEFFICIENT BEHAVIOR FOR BOUNDARY LAYER BLEED HOLES AND SLOTS

B. P. Willis, D. O. Davis, and W. R. Hingst Jan. 1995 16 p Presented at the 33rd Aerospace Sciences Meeting and Exhibit, Reno, NV, 9-12 Jan. 1995; sponsored by AIAA
(RTOP 505-62-52)
(NASA-TM-106846; E-9420; NAS 1.15:106846; AIAA Paper 95-0031)
Avail: CASI HC A03/MF A01

An experimental investigation into the flow coefficient behavior for nine boundary layer bleed orifice configurations is reported. This test was conducted for the purposes of exploring boundary layer control through mass flow removal and does not address issues of stability bleed. Parametric data consist of bleed region flow coefficient as a function of Mach number, bleed plenum pressure, and bleed orifice geometry. Seven multiple hole configurations and two single slot configurations were tested over a supersonic Mach number range of 1.3 to 2.5 (nominal). Advantages gained by using multiple holes in a bleed region instead of a single spanwise slot are discussed and the issue of modeling an entire array of bleed orifices based on the performance of a single orifice is addressed. Preconditioning the flow approaching a 90 degree inclined (normal) hole configuration resulted in a significant improvement in the performance of the configuration. The same preconditioning caused only subtle changes in performance for a 20 degree inclined (slanted) configuration. Author

Direct numerical simulation data bases for compressible homogeneous shear flow are used to evaluate the performance of recently proposed Reynolds stress closures for compressible turbulence. Three independent pressure-strain models are considered along with a variety of explicit compressible corrections that account for dilatational dissipation and pressure-dilatation effects. The ability of the models to predict both time evolving fields and equilibrium states is systematically tested. Consistent with earlier studies, it is found that the addition of simple dilatational models allows for the prediction of the reduced growth rate of turbulent kinetic energy in compressible homogeneous shear flow. However, a closer examination of the equilibrium structural parameters uncovers a major problem. None of the models are able to predict the dramatic increase in the normal Reynolds stress anisotropies or the significant decrease in the Reynolds shear stress anisotropy that arise from compressible effects. The physical origin of this deficiency is attributed to the neglect of compressible terms in the modeling of the deviatoric part of the pressure-strain correlation. DTIC

(AD-A280005; AFOSR-94-0339TR) Avail: CASI HC A05/MF A01

Numerical solutions to the Navier-Stokes equations for a 3-D, time-dependent, highly-symmetric flow have been completed. An effective resolution of up to 10243 collocation points (341 modes after dealiasing) is attained within the memory on the 256 MW CRAY-2 at Kirtland AFB and the C90 at the Pittsburgh Supercomputer Center. These simulations constitutes the highest resolution runs made to date. One of the primary purposes of the work was to create a data base from which a detailed energy transfer and triad analysis could be made by Andrzej Domaradzki at USC. The data base has been made, and runs for Reynolds numbers of 500, 1000, 2000 and 5000 have been stored on tape. We shall give some information concerning the turbulent flows later in this report. The other purpose of this work is to try to understand the transition process through which the flow becomes turbulent. Our early-time analysis of the data base of runs was concerned with this problem, and hence most of this report will deal with our findings. We also attach a manuscript on this subject that will be published shortly in The Physics of Fluids. DTIC

HINDERED SETTLING COMPUTATIONS USING A PARALLEL BOUNDARY ELEMENT METHOD

M. S. Ingber (New Mexico Univ., Albuquerque, NM.) and D. E. Womble 1994 7 p Presented at the American Society of Mechanical Engineers' Winter Annual Meeting, Chicago, IL, 9-11 Nov. 1994
(Contract DE-AC04-94AL-85000)
(DE94-014286; SAND-94-1396C; CONF-941142-10) Avail: CASI HC A02/MF A01

This paper presents a parallel implementation of the boundary element method (BEM) for multiple instruction multiple data (MIMD) computer architectures to determine the hindered settling function for a suspension of sedimenting rigid particles in Stokes flow. The hindered settling function is a measure of the average sedimentation velocity of the suspension. This function can be determined numerically by performing statistical analyses of several random realizations of a physical system characterized by a set of defining parameters. These defining parameters can include the volume fraction of the solid phase, shape factors, orientation characteristics, and others. The boundary element method is particularly well suited for studying such systems because of the simplification in the discretization associated with the method. However, as the number of solid particles to be modeled is increased so are the computational demands. Parallel computation offers the opportunity to model systems of greater complexity. We discuss a parallel boundary element formulation based on the torus-wrap mapping. In this approach, blocks of the coefficient matrix associated with the discretized boundary element equations are assigned to processors as opposed to more traditional parallel boundary element implementations where rows or columns are assigned to processors. The torus-wrap mapping can be shown to minimize the communication volume between processors during the LU factorization. Therefore, the present formulation scales well with increases in the number of processors. DOE

NONLINEAR DYNAMIC FLUID-STRUCTURE INTERACTION CALCULATIONS WITH COUPLED FINITE ELEMENT AND FINITE VOLUME PROGRAMS

M. W. Lewis, B. A. Kashiwa, R. W. Meier, and S. Bishop (Army Night Vision Lab., Fort Belvoir, VA.) 1994 11 p Presented at the American Society of Mechanical Engineers' Winter Annual Meeting, Chicago, IL, 9-11 Nov. 1994
(Contract W-7405-eng-36)
(DE94-016204; LA-UR-94-2443; CONF-941142-15) Avail: CASI HC A03/MF A01

Two- and three-dimensional fluid-structure interaction computer programs for the simulation of nonlinear dynamics were developed and applied to a number of problems. The programs were created by coupling Arbitrary Lagrangian-Eulerian finite volume fluid dynamics programs with strictly Lagrangian finite element structural dynamics programs. The resulting coupled programs can use either fully explicit or implicit time integration. The implicit time integration is accomplished by iterations of the fluid dynamics pressure solver and the structural dynamics system solver. The coupled programs have been used to solve problems involving incompressible fluids, membrane and shell elements, compressible multiphase flows, explosions in both air and water, and large displacements. In this paper, we present the approach used for the coupling and describe test problems that verify the two-dimensional programs against an experiment and an analytical linear problem. The experiment involves an explosion underwater near an instrumented thin steel plate. The analytical linear problem is the vibration of an infinite cylinder surrounded by an incompressible fluid to a given radius. DOE

CONTINUUM TRANSIENT AND FROZEN STARTUP BEHAVIOR OF CONVENTIONAL AND GAS-LOADED HEAT PIPES Final Report

Amir Faghri Feb. 1994 104 p
(Contract F33615-88-C-2820)
(AD-A284297; WL-TR-94-2044) Avail: CASI HC A06/MF A02

The heat pipe startup process is described physically and mathematically. During most of the heat pipe startup process, the continuum and rarefied vapor flows coexist along the heat pipe length. A two-region model is thereby proposed in which the vapor flow in the continuum region is modeled by the compressible Navier-Stokes equations, and the vapor flow in the rarefied region is modeled by the self-diffusion model. The two vapor regions are linked with appropriate boundary conditions, and the heat pipe wall, wick and vapor flow are solved as a conjugate problem. Both numerical and analytical solutions for the entire heat pipe startup process from the frozen state are compared with the corresponding experimental data with good agreement. DTIC

LOW FLOW FLUID SEPARATOR Patent

Michael K. Adams, inventor (to Navy) and Thomas H. Hane, inventor (to Navy) 5 Jul. 1994 7 p Filed 13 Nov. 1992
(AD-D016575; US-Patent-5,326,474; US-Patent-Appl-SN-976033; US-Patent-Class-210-519) Avail: US Patent and Trademark Office

A separator for immiscible fluids and particulate matter of differing densities provides a plurality of stages of fluid flow velocity reduction by change of cross-sectional areas between a plurality of flow regions (e.g. conduits and chambers) and separates a fraction of the introduced fluid or suspended particulate matter at each change of velocity whereby flow velocity may be reduced to a degree greater than accounted for by the change of cross-sectional area from stage to stage when significant amounts of materials to be separated are present in the input fluid. Further, a substantial effective length is provided, relative to the footprint of the separator. This length and gradual slowing of the fluids therein provides generally laminar flow and low turbulence. By doing so, overall volume of the passive separator is reduced and separation efficiency is substantially improved. DTIC

(AD-A285360; AFOSR-94-101TR) Avail: CASI HC A03/MF A01

The three-dimensional structure of the turbulent motion of fluid flowing close to a surface has been studied using the technique of linear mean square stochastic estimation to find estimates of the flow field when certain events occur in the flow. The structures given the velocity at one point have been documented, and their dynamic evolution is being studied. It is shown that they are long-lived. One-point events provide insight into the physical bases of closure approximations in one-point moment closures, and they have been used to provide a new closure approximation for the fast pressure-strain correlation. Stochastic estimation is used as a means of defining three-dimensional, dynamic wall boundary conditions for large eddy simulations. DTIC

TRANSPORT PHENOMENA IN THE MICROPORES OF PLUG-TYPE PHASE SEPARATORS
M. M. Fazah Washington Feb. 1995 58 p
(NASA-TM-108479; NAS 1.15:108479) Avail: CASI HC A04/MF A01

This study numerically investigates the transport phenomena within and across a porous-plug phase separator. The effect of temperature differential across a single pore and of the sidewall boundary conditions, i.e., isothermal or linear thermal gradient, are presented and discussed. The effects are quantified in terms of the evaporation mass flux across the boundary and the mean surface temperature. A two-dimensional finite element model is used to solve the continuity, momentum, and energy equations for the liquid. Temperature differentials across the pore interface of 1.0, and 1.5 K are examined and their effect on evaporation flux and mean surface temperature is shown. For isothermal side boundary conditions, the evaporation flux across the pore is directly proportional and linear with Delta T. For the case of an imposed linear thermal gradient on the side boundaries, Biot numbers of 0.0, 0.15, and 0.5 are examined. The most significant effect of Biot number is to lower the overall surface temperature and evaporation flux. Author

INTERNAL AERODYNAMICS OF A GENERIC THREE-DIMENSIONAL SCRAMJET INLET AT MACH 10
Scott D. Holland Jan. 1995 55 p
(RTOP 506-40-41-02)
(NASA-TP-3476; L-17347; NAS 1.60:3476) Avail: CASI HC A04/MF A01

A combined computational and experimental parametric study of the internal aerodynamics of a generic three-dimensional sidewall compression scramjet inlet configuration at Mach 10 has been performed. The study was designed to demonstrate the utility of computational fluid dynamics as a design tool in hypersonic inlet flow fields, to provide a detailed account of the nature and structure of the internal flow interactions, and to provide a comprehensive surface property and flow field database to determine the effects of contraction ratio, cowl position, and Reynolds number on the performance of a hypersonic scramjet inlet configuration. The work proceeded in several phases: the initial inviscid assessment of the internal shock structure, the preliminary computational parametric study, the coupling of the optimized configuration with the physical limitations of the facility, the wind tunnel blockage assessment, and the computational and experimental parametric study of the final configuration. Good agreement between computation and experimentation was observed in the magnitude and location of the interactions, particularly for weakly interacting flow fields. Large-scale forward separations resulted when the interaction strength was increased by increasing the contraction ratio or decreasing the Reynolds number. Author

AN AUGMENTED YOUNG-LAPLACE MODEL OF AN EVAPORATING MENISCUS IN A MICRO-CHANNEL WITH HIGH HEAT FLUX Final Report
P. C. Wayner, Jr., J. Plawsky, J. A. Schonberg, and S. DasGupta [1993] 28 p Submitted for publication
(Grant NAG3-1399)
(NASA-CR-197622; NAS 1.26:197622; RPI/CHE/NASA-5-23390-5) Avail: CASI HC A03/MF A01

High flux evaporations from a steady meniscus formed in a 2 micron channel is modeled using the augmented Young-Laplace equation. The heat flux is found to be a function of the long range van der Waals dispersion force which represents interfacial conditions between heptane and various substrates. Heat fluxes of (1.3-1.6) x 10(exp 6) W/m(exp 2) based on the width of the channel are obtained for heptane completely wetting the substrate at 100 C. Small channels are used to obtain these large fluxes. Even though the real contact angle is 0 deg, the apparent contact angle is found to vary between 24.8 deg and 25.6 deg. The apparent contact angle, which represents viscous losses near the contact line, has a large effect on the heat flow rate because of its effect on capillary suction and the area of the meniscus. The interfacial heat flux is modeled using kinetic theory for the evaporation rate. The superheated state depends on the temperature and the pressure of the liquid phase. The liquid pressure differs from the pressure of the vapor phase due to capillarity and long range van der Waals dispersion forces which are relevant in the ultra think film formed at the leading edge of the meniscus. Important pressure gradients in the thin film cause a substantial apparent contact angle for a complete wetting system. The temperature of the liquid is related to the evaporation rate and to the substrate temperature through the steady heat conduction equation. Conduction in the liquid phase is calculated using finite element analysis except in the vicinity of the thin film. A lubrication theory solution for the thin film is combined with the finite element analysis by the method of matched asymptotic expansions. Author

CONSERVATIVE SMOOTHING VERSUS ARTIFICIAL VISCOSITY
C. Guenther (Michigan Technological Univ., Houghton, MI.), D. L. Hicks (Michigan Technological Univ., Houghton, MI.), and J. W. Swegle Aug. 1994 48 p
(Contract DE-AC04-94AL-85000)
(DE95-001108; SAND-94-1853) Avail: CASI HC A03/MF A01

This report was stimulated by some recent investigations of S.P.H. (Smoothed Particle Hydrodynamics method). Solid dynamics computations with S.P.H. show symptoms of instabilities which are not eliminated by artificial viscosities. Both analysis and experiment indicate that conservative smoothing eliminates the instabilities in S.P.H. computations which artificial viscosities cannot. Questions were raised as to whether conservative smoothing might smear solutions more than artificial viscosity. Conservative smoothing, properly used, can produce more accurate solutions than the von Neumann-Richtmyer-Landshoff artificial viscosity which has been the standard for many years. The authors illustrate this using the vNR scheme on a test problem with known exact solution involving a shock collision in an ideal gas. They show that the norms of the errors with conservative smoothing are significantly smaller than the norms of the errors with artificial viscosity. DOE

HIVEL2D: A TWO-DIMENSIONAL FLOW MODEL FOR HIGH-VELOCITY CHANNELS Final Report
R. L. Stockstill and R. C. Berger Nov. 1994 55 p
(AD-A286556; WES/TR/REMR-HY-12) Avail: CASI HC A04/MF A01

A numerical flow model, HIVEL2D, has been developed as a tool to evaluate high-velocity channels. HIVEL2D is a depth-averaged, two-dimensional flow model designed specifically for flow fields that contain supercritical and subcritical regimes as well as the transitions between the regimes. The model is a finite element description of the two-dimensional shallow-water equations in conservative form. Provided in this report are a description of the numerical flow model and illustrative examples of typical high-velocity flow fields that the model is capable of simulating. Model verification is obtained by comparison of simulation results with data obtained from flume studies. Model assumptions and limitations are also discussed. DTIC

APPLICATION OF WAVELET-FILTERING TECHNIQUES TO INTERMITTENT TURBULENT AND WALL PRESSURE EVENTS. PART 1: EXPLORATORY RESULTS Progress Report, Oct. 1993 - Oct. 1994
Pablo B. Penafiel, Mario J. Casarella, and Mark Kammeyer 25 Oct. 1994 43 p
(Contract N00014-88-K-0141)
(AD-A286077) Avail: CASI HC A03/MF A01

Large amplitude wall-pressure events, observed beneath a turbulent boundary layer, appear to be the signatures of intermittent organized motions within the turbulent flow. The temporal localization of these events could be applied to the active control of turbulent wall flows. This report presents preliminary results on utilizing time-frequency localization techniques (wavelet transforms) for the detection of these events. The advantage of these methods is that they do not require a priori assumptions regarding the features of the signal. A tutorial overview of these techniques is first presented. This is followed by a discussion of some exploratory results obtained from the application of wavelet filtering to wall pressure and turbulent temporal records acquired from wind tunnel experiments. LASER ANEMOMETRY AND VISCOUS COMPUTATION OF THE FLOW THROUGH AN ANNULAR TURBINE CASCADE M.S. Thesis
Joseph D. Spitz Mar. 1994 85 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A280070) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

An annular turbine cascade, designed for laser-Doppler velocimetry, was further modified to provide additional laser and pressure probe access. The purpose of the research was to devise laser anemometry measurement techniques in a confined annulus and improve the ability to compare numerical predictions with experimental results. Flowfield computations were completed using a viscous flow solver, with the numerical exit plane coincident with experimental measurement location. A data reduction program was written to transfer nondimensional numerical output to the experimental coordinate system for comparison of total pressure ratio, Mach number and flow angle. Endwall two-dimensional laser measurements were obtained through a 1.0922 millimeter hole to a depth of approximately three millimeters. DTIC

MIXED hp FINITE ELEMENT METHODS FOR PROBLEMS IN ELASTICITY AND STOKES FLOW
Rolf Stenberg and Manil Suri (Maryland Univ. Baltimore County, Catonsville, MD.) Feb. 1994 25 p
(Contract F49620-92-J-0100)
(PB95-104444) Avail: CASI HC A03/MF A01

We consider the mixed formulation for the elasticity problem and the limiting Stokes problem. We derive a set of sufficient conditions under which families of mixed finite element spaces are simultaneously stable with respect to the mesh size h and subject to a maximum loss with respect to the polynomial degree k. We obtain asymptotic rates of convergence that are optimal in the displacement/velocity and in the pressure. Several choices of elements are discussed with reference to properties desirable in the context of the hp-version. NTIS

A COMPUTER CODE (SKINTEMP) FOR PREDICTING TRANSIENT MISSILE AND AIRCRAFT HEAT TRANSFER CHARACTERISTICS M.S. Thesis
Mary L. Cummings Sep. 1994 64 p
(AD-A286044) Avail: CASI HC A04/MF A01

A FORTRAN computer code (SKINTEMP) has been developed to calculate transient missile/aircraft aerodynamic heating parameters utilizing basic flight parameters such as altitude, Mach number, and angle of attack. The insulated skin temperature of a vehicle surface on either the fuselage (axisymmetric body) or wing (two-dimensional body) is computed from a basic heat balance relationship throughout the entire spectrum (subsonic, transonic, supersonic, hypersonic) of flight. This calculation method employs a simple finite difference procedure which considers radiation, forced convection, and non-reactive chemistry. Surface pressure estimates are based on a modified Newtonian flow model. Eckert's reference temperature method is used as the forced convection heat transfer model. SKINTEMP predictions are compared with a limited number of test cases. SKINTEMP was developed as a tool to enhance the conceptual design process of high speed missiles and aircraft. Recommendations are made for possible future development of SKINTEMP to further support the design process. DTIC

STUDYING TURBULENCE USING NUMERICAL SIMULATION DATABASES. 5: PROCEEDINGS OF THE 1994 SUMMER PROGRAM
Dec. 1994 426 p Program held in Stanford, CA, 5-29 Jul. 1994
(Contract NCC2-460)
(NASA-CR-197362; NAS 1.26:197362) Avail: CASI HC A19/MF A04

Direct numerical simulation databases were used to study turbulence physics and modeling issues at the fifth Summer Program of the Center for Turbulence Research. The largest group, comprising more than half of the participants, was the Turbulent Reacting Flows and Combustion group. The remaining participants were in three groups: Fundamentals, Modeling & LES, and Rotating Turbulence. For the first time in the CTR Summer Programs, participants included engineers from the U.S. aerospace industry. They were exposed to a variety of problems involving turbulence, and were able to incorporate the models developed at CTR in their company codes. They were exposed to new ideas on turbulence prediction, methods which already appear to have had an impact on their capabilities at their laboratories. Such interactions among the practitioners in the government, academia, and industry are the most meaningful way of transferring technology. For individual titles, see N95-21036 through N95-21060.

EFFECTS OF NON-UNITY LEWIS NUMBERS IN DIFFUSION FLAMES **c25**

A. Linan, P. Orlandi (Rome Univ., Italy.), R. Verzicco (Rome Univ., Italy.), and F. J. Higuera *In* Stanford Univ., Studying Turbulence Using Numerical Simulation Databases. 5: Proceedings of the 1994 Summer Program Dec. 1994 p 5-18 (For primary document see N95-21035 06-34)
Avail: CASI HC A03/MF A04

The purpose of this work is to carry out direct numerical simulations of diffusion controlled combustion with non-unity Lewis numbers for the reactants and products, thus accounting for the differential diffusion effects of the temperature and concentration fields. We use a formulation based on combining the conservation equations in a way to eliminate the reaction terms similar to the method used by Burke and Schumann (1928) for unity Lewis numbers. We present calculations for an axisymmetric fuel jet and for a planar, time evolving mixing layer, leaving out the effects of thermal expansion and variations of the transport coefficients due to the heat release. Our results show that the front of the flame shifts toward the fuel or oxygen sides owing to the effect of the differential diffusion and that the location of maximum temperature may not coincide with the flame. The dependence of the distribution of the reaction products on their Lewis number has been investigated. Author

EFFECT OF CHEMICAL HEAT RELEASE IN A TEMPORALLY EVOLVING MIXING LAYER **c25**

F. J. Higuera (Escuela Tecnica Superior de Ingenieros Aeronauticos, Madrid, Spain.) and R. D. Moser *In* Stanford Univ., Studying Turbulence Using Numerical Simulation Databases. 5: Proceedings of the 1994 Summer Program Dec. 1994 p 19-40 (For primary document see N95-21035 06-34)
Avail: CASI HC A03/MF A04

Two-dimensional numerical simulations of a temporally evolving mixing layer with an exothermic infinitely fast diffusion flame between two unmixed reactants have been carried out in the limit of zero Mach number to study the effect of the heat release on the early stages of the evolution of the flow. Attention has been directed to relatively large values of the oxidizer-to-fuel mass stoichiometric ratio typical of hydrocarbon flames, and initial vorticity distributions thicker than the temperature and species distributions have been chosen to mimic the situation at the outlet of a jet. The results show that, during the stages of the evolution covered by the present simulations, enhancement of combustion occurs by local stretching of the flame without much augmentation of its area. The rate of product generation depends strongly on the initial conditions, which suggests the possibility of controlling the combustion by acting on the flow. Rollup and vortex amalgamation still occur in these reacting flows but are very much affected by the production of new vorticity by baroclinic torques. These torques lead to counter rotating vortex pairs around the flame and, more importantly, in thin layers of light fluid that leave the vicinity of the flame when the Kelvin-Helmholtz instability begins to develop. Propelled by the vortex pairs, these layers wind around, split on reaching high pressure regions, and originate new vortex pairs in a process that ends up building large-scale vortices with a vorticity distribution more complex than for a constant density fluid. DIRECT NUMERICAL SIMULATIONS OF TURBULENT NON-PREMIXED METHANE-AIR FLAMES MODELED WITH REDUCED KINETICS **c25**

J. M. Card, J. H. Chen, M. Day, and S. Mahalingam (Colorado Univ., Boulder, CO.) *In its* Studying Turbulence Using Numerical Simulation Databases. 5: Proceedings of the 1994 Summer Program Dec. 1994 p 41-54 Sponsored by AWU-DOE faculty fellowship program (For primary document see N95-21035 06-34)
Avail: CASI HC A03/MF A04

Turbulent non-premixed stoichiometric methane-air flames modeled with reduced kinetics have been studied using the direct numerical simulation approach. The simulations include realistic chemical kinetics, and the molecular transport is modeled with constant Lewis numbers for individual species. The effect of turbulence on the internal flame structure and extinction characteristics of methane-air flames is evaluated. Consistent with earlier DNS with simple one-step chemistry, the flame is wrinkled and in some regions extinguished by the turbulence, while the turbulence is weakened in the vicinity of the flame due to a combination of dilatation and an increase in kinematic viscosity. Unlike previous results, reignition is observed in the present simulations. Lewis number effects are important in determining the local stoichiometry of the flame. The results presented in this work are preliminary but demonstrate the feasibility of incorporating reduced kinetics for the oxidation of methane with direct numerical simulations of homogeneous turbulence to evaluate the limitations of various levels of reduction in the kinetics and to address the formation of thermal and prompt NO(x). The stabilization of diffusion flames is studied using asymptotic techniques and numerical tools. The configuration studied corresponds to parallel streams of cold oxidizer and fuel initially separated by a splitter plate. It is shown that stabilization of a diffusion flame may only occur in this situation by two processes. First, the flame may be stabilized behind the flame holder in the wake of the splitter plate. For this case, numerical simulations confirm scalings previously predicted by asymptotic analysis. Second, the flame may be lifted. In this case a triple flame is found at longer distances downstream of the flame holder. The structure and propagation speed of this flame are studied by using an actively controlled numerical technique in which the triple flame is tracked in its own reference frame. It is then possible to investigate the triple flame structure and velocity. It is shown, as suggested from asymptotic analysis, that heat release may induce displacement speeds of the triple flame larger than the laminar flame speed corresponding to the stoichiometric conditions prevailing in the mixture approaching the triple flame. In addition to studying the characteristics of triple flames in a uniform flow, their resistance to turbulence is investigated by subjecting triple flames to different vortical configurations. TURBULENT TRANSPORT IN PREMIXED FLAMES **c25**

C. J. Rutland and R. S. Cant (Manchester Coll. of Science and Technology, England.) *In* Stanford Univ., Studying Turbulence Using Numerical Simulation Databases. 5: Proceedings of the 1994 Summer Program Dec. 1994 p 75-94 (For primary document see N95-21035 06-34)
Avail: CASI HC A03/MF A04

Simulations of planar, premixed turbulent flames with heat release were used to study turbulent transport. Reynolds stress and Reynolds flux budgets were obtained and used to guide the investigation of important physical effects. Essentially all pressure terms in the transport equations were found to be significant. In the Reynolds flux equations, these terms are the major source of counter-gradient transport. Viscous and molecular terms were also found to be significant, with both dilatational and solenoidal terms contributing to the Reynolds stress dissipation. The BML theory of premixed turbulent combustion was critically examined in detail. The BML bimodal pdf was found to agree well with the DNS data. All BML decompositions, through the third moments, show very good agreement with the DNS results. Several BML models for conditional terms were checked using the DNS data and were found to require more extensive development. Author

THE COUPLING BETWEEN FLAME SURFACE DYNAMICS AND SPECIES MASS CONSERVATION IN PREMIXED TURBULENT COMBUSTION **c25**

A. Trouve (Institut Francais du Petrole, Paris.), D. Veynante (Ecole Centrale de Paris, France.), K. N. C. Bray (Cambridge Univ., Cambridge, England.), and T. Mantel *In* Stanford Univ., Studying Turbulence Using Numerical

Simulation Databases. 5: Proceedings of the 1994 Summer Program Dec. 1994 p 95-124 (For primary document see N95-21035 06-34)
Avail: CASI HC A03/MF A04

Current flamelot models based on a description of the flame surface dynamics require the closure of two inter-related equations: a transport equation for the mean reaction progress variable, (tilde)c, and a transport equation for the flame surface density, Sigma. The coupling between these two equations is investigated using direct numerical simulations (DNS) with emphasis on the correlation between the turbulent fluxes of (tilde)c, bar(pu"c"), and Sigma, (u")(sub S)Sigma. Two different DNS databases are used in the present work: a database developed at CTR by A. Trouve and a database developed by C. J. Rutland using a different code. Both databases correspond to statistically one-dimensional premixed flames in isotropic turbulent flow. The run parameters, however, are significantly different, and the two databases correspond to different combustion regimes. It is found that in all simulated flames, the correlation between bar(pu"c") and (u")(sub S)Sigma is always strong. The sign, however, of the turbulent flux of (tilde)c or Sigma with respect to the mean gradients, delta(tilde)c/delta(x) or delta(Sigma)/delta(x), is case-dependent. The CTR database is found to exhibit gradient turbulent transport of (tilde)c and Sigma, whereas the Rutland DNS features counter-gradient diffusion. The two databases are analyzed and compared using various tools (a local analysis of the flow field near the flame, a classical analysis of the conservation equation for (tilde)(u"c"), and a thin flame theoretical analysis). A mechanism is then proposed to explain the discrepancies between the two databases and a preliminary simple criterion is derived to predict the occurrence of gradient/counter-gradient turbulent diffusion. Pdf MODELING FOR PREMIXED TURBULENT COMBUSTION BASED ON THE PROPERTIES OF ISO-CONCENTRATION SURFACES **c25**

L. Vervisch, W. Kollmann (California Univ., Davis, CA.), K. N. C. Bray (Cambridge Univ., Cambridge, England.), and T. Mantel *In* Stanford Univ., Studying Turbulence Using Numerical Simulation Databases. 5: Proceedings of the 1994 Summer Program Dec. 1994 p 125-150 (For primary document see N95-21035 06-34)
Avail: CASI HC A03/MF A04

In premixed turbulent flames the presence of intense mixing zones located in front of and behind the flame surface leads to a requirement to study the behavior of iso-concentration surfaces defined for all values of the progress variable (equal to unity in burnt gases and to zero in fresh mixtures). To support this study, some theoretical and mathematical tools devoted to level surfaces are first developed. Then a database of direct numerical simulations of turbulent premixed flames is generated and used to investigate the internal structure of the flame brush, and a new pdf model based on the properties of iso-surfaces is proposed. We analyze results of a premixed constant density flame propagating in three-dimensional turbulence, where a flame model developed by Kerstein, et al. (1988) has been used. Simulations with constant and evolving velocity fields are used, where peculiar results were obtained from the constant velocity field runs. Data from the evolving flow runs with various flame speeds are used to determine two-point correlations of the fluctuating scalar field and implications for flamelet modeling are discussed. Author

SIMULATION OF A TURBULENT FLAME IN A CHANNEL **c25**

G. Bruneaux, K. Akselvoll (Stanford Univ., CA.), T. Poinsot (Institut de Mecanique des Fluides de Toulouse, France.), and J. H. Ferziger (Stanford Univ., CA.) *In* Stanford Univ., Studying Turbulence Using Numerical Simulation Databases. 5: Proceedings of the 1994 Summer Program Dec. 1994 p 157-174 (For primary document see N95-21035 06-34)
Avail: CASI HC A03/MF A04

The interaction between turbulent premixed flames and channel walls is studied. Combustion is represented by a simple irreversible reaction with a large activation temperature. Feedback to the flowfield is suppressed by invoking a constant density assumption. The effect of wall distance on local and global flame structure is investigated. Quenching distances and maximum wall heat fluxes computed in laminar cases are compared to DNS results. It is found that quenching distances decrease and maximum heat fluxes increase relative to laminar flame values. It is shown that these effects are due to large coherent structures which push flame elements towards to wall. The effect of wall strain is studied in flame-wall interaction in a stagnation line flow; this is used to explain the DNS results. It is also shown that 'remarkable' flame events are produced by interaction with a horseshoe vortex: burnt gases are pushed towards the wall at high speed and induce quenching and high wall heat fluxes while fresh gases are expelled from the wall region and form finger-like structures. Effects of the wall on flame surface density are investigated, and a simple model for flame-wall interaction is proposed; its predictions compare well with the DNS results. Author

PRESSURE AND HIGHER-ORDER SPECTRA FOR HOMOGENEOUS ISOTROPIC TURBULENCE

D. I. Pullin (Stanford Univ., CA.) and R. S. Rogallo *In* Stanford Univ., Studying Turbulence Using Numerical Simulation Databases. 5: Proceedings of the 1994 Summer Program Dec. 1994 p 177-187 (For primary document see N95-21035 06-34)
Avail: CASI HC A03/MF A04

The spectra of the pressure, and other higher-order quantities including the dissipation, the enstrophy, and the square of the longitudinal velocity derivative are computed using data obtained from direct numerical simulation of homogeneous isotropic turbulence at Taylor-Reynolds numbers R(sub lambda) in the range 38 - 170. For the pressure spectra we find reasonable collapse in the dissipation range (of the velocity spectrum) when scaled in Kolmogorov variables and some evidence, which is not conclusive, for the existence of a k(exp -7/3) inertial range where k = absolute value of K, is the modulus of the wavenumber. The power spectra of the dissipation, the enstrophy, and the square of the longitudinal velocity derivative separate in the dissipation range, but appear to converge together in the short inertial range of the simulations. A least-squares curve-fit in the dissipation range for one value of R(sub lambda) = 96 gives a form for the spectrum of the dissipation as k(exp 0)exp(-Ck eta), for k(eta) greater than 0.2, where eta is the Kolmogorov length and C is approximately equal to 2.5. STATISTICS OF PRESSURE AND PRESSURE GRADIENT IN HOMOGENEOUS ISOTROPIC TURBULENCE

T. Gotoh (Nagoya Inst. of Tech., Japan.) and R. S. Rogallo *In* Stanford Univ., Studying Turbulence Using Numerical Simulation Databases. 5: Proceedings of the 1994 Summer Program Dec. 1994 p 189-205 (For primary document see N95-21035 06-34)
Avail: CASI HC A03/MF A04

The statistics of pressure and pressure gradient in stationary isotropic turbulence are measured within direct numerical simulations at low to moderate Reynolds numbers. It is found that the one-point pdf of the pressure is highly skewed and that the pdf of the pressure gradient is of stretched exponential form. The power spectrum of the pressure P(k) is found to be larger than the corresponding spectrum P(sub G)(k) computed from a Gaussian velocity field having the same energy spectrum as that of the DNS field. The ratio P(k)/P(sub G)(k), a measure of the pressure-field intermittence, grows with wavenumber and Reynolds number as -R(sub lambda)(exp 1/2)log(k/k(sub d)) for k less than k(sub d)/2 where k(sub d) is the Kolmogorov wavenumber. The Lagrangian correlations of pressure gradient and velocity are compared and the Lagrangian time scale of the pressure gradient is observed to be much shorter than that of the velocity. Author

THE DECAY OF AXISYMMETRIC HOMOGENEOUS TURBULENCE

J. R. Chasnov *In* Stanford Univ., Studying Turbulence Using Numerical Simulation Databases. 5: Proceedings of the 1994 Summer Program Dec. 1994 p 207-219 (For primary document see N95-21035 06-34)
Avail: CASI HC A03/MF A04

The decay of a homogeneous turbulence generated by an axisymmetric distribution of random impulsive forces acting at the initial instant is considered. The impulsive forces may be either parallel or perpendicular to the symmetry axis. For impulsive forces which result in a kappa(exp 4) low wavenumber energy spectrum of the turbulence, it is determined that the flow approaches isotropy on all scales of motion at long-times provided the Reynolds number is large. However, for the type of impulsive forces originally proposed by Saffman in which a sq kappa low wavenumber energy spectrum is produced, the turbulence approaches isotropy only at the smallest scales and remains significantly anisotropic at the largest and energy-containing scales. Nevertheless, a similarity state of the flow field establishes itself asymptotically, in which the kinetic energy per unit mass of the turbulence decays as t(exp -6/5). Author

VORTEX RING INSTABILITY AND ITS SOUND

R. Verzicco (Rome Univ., Italy.) and K. Shariff *In* Stanford Univ., Studying Turbulence Using Numerical Simulation Databases. 5: Proceedings of the 1994 Summer Program Dec. 1994 p 221-228 (For primary document see N95-21035 06-34)
Avail: CASI HC A02/MF A04

This work carries earlier finite-difference calculations of the Widnall instability of vortex rings into the late non-linear stage. Plots of energy in azimuthal Fourier modes indicate that low-order modes dominate at large times; their structure and dynamics remain unexplored, however. An attempt was made to calculate the acoustic signal using the theory of Mohring (1978), valid for unbounded flow. This theory shows that only low-order azimuthal modes contribute to the sound. As a check on the effects of axial periodicity and a slip wall at large radius imposed by the numerical scheme, the acoustic integrals were also computed in a truncated region. Half of the terms contributing to the sound have large differences between the two regions, and the results are therefore unreliable. The error is less severe for a contribution involving only the m = 2 mode, and its low frequency is consistent with a free elliptic bending wave on a thin ring. Author

INSTABILITY OF STREAMWISE VORTICES IN PLANE CHANNEL FLOWS

K. Coughlin (Montreal Univ., Quebec.), J. Jimenez (Stanford Univ., CA.), and R. D. Moser *In* Stanford Univ., Studying Turbulence Using Numerical Simulation Databases. 5: Proceedings of the 1994 Summer Program Dec. 1994 p 229-244 (For primary document see N95-21035 06-34)
Avail: CASI HC A03/MF A04

We present analysis and numerical experiments on the instability of streamwise vortices in 'minimal channel' flows and argue that this instability is a key feature in the observed intermittent cycle of formation, break-up, and re-formation of these structures. The base flow is a three-component, two-dimensional pair of counter-rotating rolls with axes aligned along the direction of the mean shear. While it is not a steady solution to the Navier-Stokes equations, we show numerically that this flow is unstable on a fast time scale to a secondary, three-dimensional Floquet mode. The growth of the secondary instability does not saturate in a new equilibrium, but continues until highly unstable local shear layers form and the entire flow breaks down into turbulence. Our analysis is motivated in part by the strong similarities between the intermittent turbulent cycle in minimal channel flows and one studied, both experimentally and in computations, in Couette-Taylor flow. NUMERICAL INVESTIGATION OF SUPERSONIC TURBULENT BOUNDARY LAYERS WITH HIGH WALL TEMPERATURE

Y. Guo and N. A. Adams (Stanford Univ., CA.) *In* Stanford Univ., Studying Turbulence Using Numerical Simulation Databases. 5: Proceedings of the 1994 Summer Program Dec. 1994 p 245-267 (For primary document see N95-21035 06-34)
Avail: CASI HC A03/MF A04

A direct numerical approach has been developed to simulate supersonic turbulent boundary layers. The mean flow quantities are obtained by solving the parabolized Reynolds-averaged Navier-Stokes equations (globally). Fluctuating quantities are computed locally with a temporal direct numerical simulation approach, in which nonparallel effects of boundary layers are partially modeled. Preliminary numerical results obtained at the free-stream Mach numbers 3, 4.5, and 6 with hot-wall conditions are presented. Approximately 5 million grid points are used in all three cases. The numerical results indicate that compressibility effects on turbulent kinetic energy, in terms of dilatational dissipation and pressure-dilatation correlation, are small. Due to the hot-wall conditions the results show significant low Reynolds number effects and large streamwise streaks. Further simulations with a bigger computational box or a cold-wall condition are desirable. Author

A LAGRANGIAN DYNAMIC SUBGRID-SCALE MODEL TURBULENCE

C. Meneveau, T. S. Lund (Stanford Univ., CA.), and W. Cabot (Stanford Univ., CA.) *In* Stanford Univ., Studying Turbulence Using Numerical Simulation Databases. 5: Proceedings of the 1994 Summer Program Dec. 1994 p 271-299 (For primary document see N95-21035 06-34)
Avail: CASI HC A03/MF A04

A new formulation of the dynamic subgrid-scale model is tested in which the error associated with the Germano identity is minimized over flow pathlines rather than over directions of statistical homogeneity. This procedure allows the application of the dynamic model with averaging to flows in complex geometries that do not possess homogeneous directions. The characteristic Lagrangian time scale over which the averaging is performed is chosen such that the model is purely dissipative, guaranteeing numerical stability when coupled with the Smagorinsky model. The formulation is tested successfully in forced and decaying isotropic turbulence and in fully developed and transitional channel flow. In homogeneous flows, the results are similar to those of the volume-averaged dynamic model, while in channel flow, the predictions are superior to those of the plane-averaged dynamic model. The relationship between the averaged terms in the model and vortical structures (worms) that appear in the LES is investigated. Computational overhead is kept small (about 10 percent above the CPU requirements of the volume or plane-averaged dynamic model) by using an approximate scheme to advance the Lagrangian tracking through first-order Euler time integration and linear interpolation in space. EFFECTS OF TURBULENCE COMPRESSIBILITY AND UNSTEADINESS IN COMPRESSION CORNER FLOW

A. Brankovic and O. Zeman (Stanford Univ., CA.) *In* Stanford Univ., Studying Turbulence Using Numerical Simulation Databases. 5: Proceedings of the 1994 Summer Program Dec. 1994 p 301-311 (For primary document see N95-21035 06-34)
Avail: CASI HC A03/MF A04

The structure of the separated flow region over a 20 degree compression corner at a free-stream Mach number of 2.84 is investigated computationally using a Reynolds averaged Navier Stokes (R.A.N.S.) solver and kappa-epsilon model. At this Mach number and ramp angle, a steady-state recirculation region of order delta(sub o) is observed, with onset of a 'plateau' in the wall pressure distribution near the corner. At lower ramp angles, separation is negligible, while at an angle of 24 degrees, separation regions of length 2 delta(sub o) are expected. Of interest here is the response of the mathematical model to inclusion of the pressure dilatation term for turbulent kinetic energy. Compared with the experimental data of Smits and Muck (1987), steady-state computations show improvement when the pressure dilatation term is included. Unsteady computations, using both unforced and then forced inlet conditions, did not predict the oscillatory motion of the separation bubble as observed in laboratory experiments. An analysis of the separation bubble oscillation and the turbulent boundary layer (T.B.L.) frequencies for this flow suggests that the bubble oscillations are of nearly the same order as the turbulent frequencies, and therefore difficult for the model to separate and resolve. Author

ROLE OF PRESSURE DIFFUSION IN NON-HOMOGENEOUS SHEAR FLOWS

A. O. Demuren, S. K. Lele (Stanford Univ., CA.), and P. Durbin (Stanford Univ., CA.) *In* Stanford Univ., Studying Turbulence Using Numerical Simulation Databases. 5: Proceedings of the 1994 Summer Program Dec. 1994 p 313-321 (For primary document see N95-21035 06-34)

Avail: CASI HC A02/MF A04

A non-local model is presented for approximating the pressure diffusion in calculations of turbulent free shear and boundary layer flows. It is based on the solution of an elliptic relaxation equation which enables local diffusion sources to be distributed over lengths of the order of the integral scale. The pressure diffusion model was implemented in a boundary layer code within the framework of turbulence models based on both the kappa-epsilon-(bar)upsilon(exp 2) system of equations and the full Reynolds stress equations. Model computations were performed for mixing layers and boundary layer flows. In each case, the pressure diffusion model enabled the well-known free-stream edge singularity problem to be eliminated. There was little effect on near-wall properties. Computed results agreed very well with experimental and DNS data for the mean flow velocity, the turbulent kinetic energy, and the skin-friction coefficient. Author

MODELING NEAR WALL EFFECTS IN SECOND MOMENT CLOSURES BY ELLIPTIC RELAXATION

D. Laurence and P. Durbin (Stanford Univ., CA.) *In* Stanford Univ., Studying Turbulence Using Numerical Simulation Databases. 5: Proceedings of the 1994 Summer Program Dec. 1994 p 323-338 (For primary document see N95-21035 06-34)

Avail: CASI HC A03/MF A04

The elliptic relaxation model of Durbin (1993) for modeling near-wall turbulence using second moment closures (SMC) is compared to DNS data for a channel flow at Re(sub t) = 395. The agreement for second order statistics and even the terms in their balance equation is quite satisfactory, confirming that very little viscous effects (via Kolmogoroff scales) need to be added to the high Reynolds versions of SMC for near-wall-turbulence. The essential near-wall feature is thus the kinematic blocking effect that a solid wall exerts on the turbulence through the fluctuating pressure, which is best modeled by an elliptic operator. Above the transition layer, the effect of the original elliptic operator decays rapidly, and it is suggested that the log-layer is better reproduced by adding a non-homogeneous reduction of the return to isotropy, the gradient of the turbulent length scale being used as a measure of the inhomogeneity of the log-layer. The elliptic operator was quite easily applied to the non-linear Craft & Launder pressure-strain model yielding an improved distinction between the spanwise and wall normal stresses, although at higher Reynolds number (Re) and away from the wall, the streamwise component is severely underpredicted, as well as the transition in the mean velocity from the log to the wake profiles. In this area a significant change of behavior was observed in the DNS pressure-strain term, entirely ignored in the models. Author

MODELING THE TWO-POINT CORRELATION OF THE VECTOR STREAM FUNCTION

M. Oberlack (Technische Hochschule, Aachen, Germany.), M. M. Rogers, and W. C. Reynolds (Stanford Univ., CA.) *In* Stanford Univ., Studying Turbulence Using Numerical Simulation Databases. 5: Proceedings of the 1994 Summer Program Dec. 1994 p 339-352 (For primary document see N95-21035 06-34)

Avail: CASI HC A03/MF A04

A new model for the two-point vector stream function correlation has been developed using tensor invariant arguments and evaluated by the comparison of model predictions with DNS data for incompressible homogeneous turbulent shear flow. This two-point vector stream function model correlation can then be used to calculate the two-point velocity correlation function and other quantities useful in turbulence modeling. The model assumes that the two-point vector stream function correlation can be written in terms of the separation vector and a new tensor function that depends only on the magnitude of the separation vector. The model has a single free model coefficient, which has been chosen by comparison with the DNS data. The relative error of the model predictions of the two-point vector stream function correlation is only a few percent for a broad range of the model coefficient. Predictions of the derivatives of this correlation, which are of interest in turbulence modeling, may not be this accurate. Author

HOMOGENEOUS TURBULENCE SUBJECTED TO MEAN FLOW WITH ELLIPTIC STREAMLINES

G. A. Blaisdell and K. Shariff (Purdue Univ., West Lafayette, IN.) *In* Stanford Univ., Studying Turbulence Using Numerical Simulation Databases. 5: Proceedings of the 1994 Summer Program Dec. 1994 p 355-371 (For primary document see N95-21035 06-34)

Avail: CASI HC A03/MF A04

Direct numerical simulations are performed for homogeneous turbulence with a mean flow having elliptic streamlines. This flow combines the effects of rotation and strain on the turbulence. Qualitative comparisons are made with linear theory for cases with high Rossby number. The nonlinear transfer process is monitored using a generalized skewness. In general, rotation turns off the nonlinear cascade; however, for moderate ellipticities and rotation rates the nonlinear cascade is turned off and then reestablished. Turbulence statistics of interest in turbulence modeling are calculated, including full Reynolds stress budgets. Author

ON THE TRANSITION TOWARDS SLOW MANIFOLD IN SHALLOW-WATER AND 3D EULER EQUATIONS IN A ROTATING FRAME

A. Mahalov *In* Stanford Univ., Studying Turbulence Using Numerical Simulation Databases. 5: Proceedings of the 1994 Summer Program Dec. 1994 p 373-382 (For primary document see N95-21035 06-34)

Avail: CASI HC A02/MF A04

The long-time, asymptotic state of rotating homogeneous shallow-water equations is investigated. Our analysis is based on long-time averaged rotating shallow-water equations describing interactions of large-scale, horizontal, two-dimensional motions with surface inertial-gravity waves field for a shallow, uniformly rotating fluid layer. These equations are obtained in two steps: first by introducing a Poincare/Kelvin linear propagator directly into classical shallow-water equations, then by averaging. The averaged equations describe interaction of wave fields with large-scale motions on time scales long compared to the time scale 1/f(sub o) introduced by rotation (f(sub o)/2-angular velocity of background rotation). The present analysis is similar to the one presented by Waleffe (1991) for 3D Euler equations in a rotating frame. However, since three-wave interactions in rotating shallow-water equations are forbidden, the final equations describing the asymptotic state are simplified considerably. Special emphasis is given to a new conservation law found in the asymptotic state and decoupling of the dynamics of the divergence free part of the velocity field. The possible rising of a decoupled dynamics in the asymptotic state is also investigated for homogeneous turbulence subjected to a background rotation. In our analysis we use long-time expansion, where the velocity field is decomposed into the 'slow manifold' part (the manifold which is unaffected by the linear 'rapid' effects of rotation or the inertial waves) and a formal 3D disturbance. We derive the physical space version of the long-time averaged equations and consider an invariant, basis-free derivation. This formulation can be used to generalize Waleffe's (1991) helical decomposition to viscous inhomogeneous flows (e.g. problems in cylindrical geometry with no-slip boundary conditions on the cylinder surface and homogeneous in the vertical direction). ON THE ASYMPTOTIC SIMILARITY OF ROTATING HOMOGENEOUS TURBULENCE

K. D. Squires (Vermont Univ., Burlington, VT.), J. R. Chasnov (Hong Kong Univ. of Science and Technology, Kowloon, Hong Kong.), and N. N. Mansour *In* Stanford Univ., Studying Turbulence Using Numerical Simulation Databases. 5: Proceedings of the 1994 Summer Program Dec. 1994 p 383-395 (For primary document see N95-21035 06-34)

Avail: CASI HC A03/MF A04

Asymptotic similarity states at large Reynolds numbers and small Rossby numbers in rotating homogeneous turbulence are investigated using the database obtained from large-eddy simulations of the incompressible Navier-Stokes equations. Previous work has shown that the turbulence kinetic energy and integral length scales are accurately described by simple scaling laws based on the low wavenumbers part of the three-dimensional energy spectrum. The primary interest of the present study is to search for spectrum similarity in the asymptotic state. Four independent energy spectra are defined. It is shown that rescaling of these energy spectra in the asymptotic regime will collapse three out of the four spectra. The spectrum which does not collapse is a function only of the vertical wavenumber and corresponds to two-component motions in the plane normal to the rotation axis. Detailed investigation of the cause of this anomalous behavior reveals the existence of a strong reverse cascade of energy from small-to-large scales of the two-dimensional, two-component motions. This feature of the rotating flow is presumably linked to the lack of a complete similarity state, though further study of this issue is required. Author

Large-eddy simulation results are used to investigate the development of anisotropies and the possible transition towards a quasi two-dimensional state in rotating turbulence at high Reynolds number. The present study demonstrates the existence of two transitions that are identified by two Rossby numbers. The first transition marks the onset of anisotropic effects and corresponds to a macro Rossby number Ro(sup L) (based on a longitudinal integral length scale) near unity. A second transition can be defined in terms of a lower bound of micro-Rossby number Ro(sup w) also near unity (defined in this work as the ratio of the rms fluctuating vorticity to background vorticity) and corresponds to a continued development of anisotropy but with an increasing emergence of those indicators based on the pure two-dimensional component of the flow, e.g., integral length scales measured along the rotation axis. Investigation of the vorticity structure shows that the second transition is also characterized by an increasing tendency for alignment between the fluctuating vorticity vector and the basic angular velocity vector with a preference for corotative vorticity. A model for the effects of rotation on turbulence is proposed and tested. These effects which influence mainly the rate of turbulence decay are modeled in a modified turbulent energy dissipation rate equation that has explicit dependence on the mean rotation rate. An appropriate definition of the rotation rate derived from critical point theory and based on the invariants of the deformation tensor is proposed. The modeled dissipation rate equation is numerically well behaved and can be used in conjunction with any level of turbulence closure. The model is applied to the two-equation kappa-epsilon turbulence model and is used to compute separated flows in a backward-facing step and an axisymmetric swirling coaxial jets into a sudden expansion. In general, the rotation modified dissipation rate model shows some improvements over the standard kappa-epsilon model. Author

The papers prepared for the AGARD Fluid Dynamics Panel (FDP) Symposium on 'Application of Direct and Large Eddy Simulation to Transition and Turbulence', which was held April 1994 in Greece are contained in this report. In addition, a Technical Evaluator's Report assessing the success of the Symposium objectives, and an edited transcript of the General Discussion are also included. In the past two decades significant progress has been made in the numerical simulation of turbulent flows. Vast improvements in speed and memory size of modern supercomputers, and recent progress in simulation algorithms and parallel computation have put us on the threshold of being able to simulate flows in configurations of engineering interest. For individual titles, see N95-21062 through N95-21098.

DEVELOPMENTS AND APPLICATIONS OF DYNAMIC MODELS FOR LARGE EDDY SIMULATION OF COMPLEX FLOWS

P. Moin, D. Carati, T. Lund, S. Ghosal, and K. Akselvoll *In* AGARD, Application of Direct and Large Eddy Simulation to Transition and Turbulence Dec. 1994 9 p Prepared in cooperation with Stanford Univ., CA Sponsored by ONR and AFOSR (For primary document see N95-21061 06-34)

Copyright Avail: CASI HC A02/MF A04

The dynamic modeling procedure for large eddy simulation of turbulent flows is reviewed and recent developments in the theoretical aspects and applications are described. Methods for inclusion of backscatter of energy from small to large scale motions are presented. New formulations of the dynamic procedure are proposed which are optimized based on the subgrid scale flux vector or the energy dissipation rate instead of the subgrid scale stress tensor. Recent results from application of the model to forced isotropic turbulence with an inertial subrange, flow over a backward facing step at Reynolds number of 28000, and flow over a concave curved surface are presented. The dynamic subgrid scale model had been used in the Large Eddy Simulation (LES) of turbulent flow in a straight square duct. The Reynolds numbers considered, (based on the friction velocity and the duct halfwidth), are varying from 150 to 1125. The results obtained are in good agreement with the reference Direct Numerical Simulation (DNS) and experimental data. The accuracy and suitability of the model in high Reynolds number finite difference computations of three dimensional non-equilibrium flows is investigated. The influence of approximate wall boundary conditions in such flow cases is also addressed. Author

Most applications of the dynamic subgrid-scale stress model use volume- or planar-averaging to avoid ill-conditioning of the model coefficient, which may result in numerical instabilities. A spatially-varying coefficient is also mathematically inconsistent with the model derivation. A localization procedure is proposed here that removes the mathematical inconsistency to any desired order of accuracy in time. This model is applied to the simulation of rotating channel flow, and results in improved prediction of the turbulence statistics. Author

THE ASYMPTOTIC STATE OF ROTATING HOMOGENEOUS TURBULENCE AT HIGH REYNOLDS NUMBERS

Kyle D. Squires (Vermont Univ., Burlington, VT.), Jeffrey R. Chasnov (Hong Kong Univ. of Science and Technology, Clear Water Bay, Hong Kong.), Nagi N. Mansour, and Claude Cambon (Ecole Centrale de Lyon, France.) *In* AGARD, Application of Direct and Large Eddy Simulation to Transition and Turbulence Dec. 1994 9 p Prepared in cooperation with Stanford Univ., CA Sponsored in part by the American Society for Engineering Education (For primary document see N95-21061 06-34)
Copyright Avail: CASI HC A02/MF A04

The long-time, asymptotic state of rotating homogeneous turbulence at high Reynolds numbers has been examined using large-eddy simulation of the incompressible Navier-Stokes equations. The simulations were carried out using 128 x 128 x 512 collocation points in a computational domain that is four times longer along the rotation axis than in the other directions. Subgrid-scale motions in the simulations were parameterized using a spectral eddy viscosity modified for system rotation. Simulation results show that in the asymptotic state the turbulence kinetic energy undergoes a power-law decay with an exponent which is independent of rotation rate, depending only on the low-wavenumber form of the initial energy spectrum. Integral lengthscale growth in the simulations is also characterized by power-law growth; the correlation length of transverse velocities exhibiting much more rapid growth than observed in non-rotating turbulence. COMPARISON OF DNS AND LES OF TRANSITIONAL AND TURBULENT COMPRESSIBLE FLOW: FLAT PLATE AND MIXING LAYER

Bernard Geurts, Bert Vreman, and Hans Kuerten *In* AGARD, Application of Direct and Large Eddy Simulation to Transition and Turbulence Dec. 1994 14 p (For primary document see N95-21061 06-34)
Copyright Avail: CASI HC A03/MF A04

We present a priori and a posteriori test results of LES (large eddy simulation) of compressible flow over a flat plate and in a mixing layer. Through a comparison with filtered DNS (direct numerical simulation) data the 'quality' of subgrid-models for the turbulent stress can be assessed. In particular, the scale similarity model of Bardina and the dynamic mixed model arising from a combination of Bardina's model with the Germano eddy-viscosity model show excellent correlations a priori, and give rise to accurate LES simulations a posteriori. Moreover, the filtering approach close to solid walls is considered and the contribution to the filtered equations arising from the non-commutation of the filter operator with the partial derivatives is calculated. It appears, in a priori tests for 2D simulations, that these non-commutation terms can be comparable to the turbulent stress. The scale similarity hypothesis yields models for these terms which show a good correlation. Author

DIRECT NUMERICAL SIMULATION OF TURBULENT FLOW IN A SUDDEN PIPE EXPANSION

C. Wagner and R. Friedrich *In* AGARD, Application of Direct and Large Eddy Simulation to Transition and Turbulence Dec. 1994 11 p (For primary document see N95-21061 06-34)
Copyright Avail: CASI HC A03/MF A04

Direct numerical simulations (DNS) of fully developed turbulent pipe flow and sudden pipe expansion flow with an expansion ratio of ER = 1.2 have been performed. The former DNS provides inflow conditions for the latter. The upstream Reynolds number, based on friction velocity and pipe diameter is 360 or 6950 based on mean centerline velocity. This is too low a Reynolds number to obtain a universal logarithmic law of the wall. Moreover, transverse curvature effects are observed when the data are compared with DNS data of Kim, Moin, Moser in the plane channel. The reason for these effects is that the streak spacing is of the same order of magnitude as the pipe radius. Hence, the pipe expansion flow will also reflect transverse curvature effects. The mean reattachment length is 10.1 step heights. Instantaneous and statistical flow variables are presented. They give an impression of the complex flow dynamics in the free shear layer, the recirculation and reattachment regions. Author

Smagorinsky and structure-function models are applied to the large eddy simulation of the turbulent flow over a cavity at a Reynolds number Re = 63,600. The near-wall flow region is modeled by implementing either a logarithmic law-of-the-wall or an exponential damping function. Results obtained with two values of the Smagorinsky constant, C(sub s) = 0.10 and 0.20, have been compared. Further, the results provided by the mentioned subgrid-scale models are compared with those obtained using the standard kappa-epsilon model. As a basis for the comparison, LDV measurements of mean and fluctuating turbulent quantities are also reported. The computational results have demonstrated that the use of large eddy simulation is clearly rewarding in face of kappa-epsilon model computation, yielding better results employing a similar number of grid nodes. LARGE-EDDY SIMULATION OF SEPARATED FLOW IN A RIBBED DUCT

Harald Braun, Martin Fiebig, and Nimai Kumar Mitra *In* AGARD, Application of Direct and Large Eddy Simulation to Transition and Turbulence Dec. 1994 9 p Sponsored by Deutsche Forschungsgemeinschaft (For primary document see N95-21061 06-34)
Copyright Avail: CASI HC A02/MF A04

Large-eddy simulation of turbulent channel flows over a one-sided periodically ribbed wall has been performed. Large-scale nonsteady structures have been correlated with the statistical values of the turbulent flow field. It is shown, that high turbulent kinetic energy and vortex shedding appear at the same location. The shedding of vortical structures from the edge of the rib is the dominating turbulent phenomena of the flow. The instantaneous behavior of the large-scale vortical structures is visualized and their interaction with the highly fluctuating recirculation zones is observed. Author

Direct and large eddy simulations of forced and decaying isotropic turbulence have been performed using a pseudospectral and a finite-difference code. Subgrid models that include a one-equation subgrid kinetic energy model with and without a stochastic backscatter forcing term and a new scale similarity model have been analyzed in both Fourier space and physical space. The Fourier space analysis showed that the energy transfer across the cutoff wavenumber k(sub c) is dominated by local interaction. The correlation between the exact and the modeled (by a spectral eddy viscosity) nonlinear terms and the subgrid energy transfer in physical space was found to be quite low. In physical space, a similar correlation analysis was carried out using top hat filtering. Results show that the subgrid stress and the energy flux predicted by the subgrid models correlates very well with the exact data. The scale similarity model showed very high correlation for reasonable grid resolution. However, with decrease in grid resolution, the scale similarity model became more uncorrelated, when compared to the kinetic energy subgrid model. The subgrid models were then used for large-eddy simulations for a range of Reynolds number. It was determined that the dissipation was modeled poorly and that the correlation with the exact results was quite low for all the models. In general, for coarse grid resolution, the scale similarity model consistently showed very low correlation while the kinetic energy model showed a relatively higher correlation. These results suggest that to use the scale similarity model relatively fine grid resolution may be required, whereas, the kinetic energy model could be used even in coarse grid. Author

A CHEAP DNS TOOL FOR TURBULENCE MODELS TESTING

A. Baron and M. Quadrio *In* AGARD, Application of Direct and Large Eddy Simulation to Transition and Turbulence Dec. 1994 10 p Sponsored by Ministero dell'Univ. e della Ricerca Scientifica e Tecnologica and Consorzio Interuniv. Lombardo per l'Elaborazione Automatica (For primary document see N95-21061 06-34)
Copyright Avail: CASI HC A02/MF A04

The Narrow Channel (NC) assumption, together with a simple although efficient numerical scheme are adopted in order to perform the Direct Numerical Simulation (DNS) of turbulent channel flows at moderate Reynolds numbers with extremely reduced computational resources. Typical results are presented for a constant property fluid, which certify the reliability of the numerical tool and the quality of the simulations. The closure problem of turbulence modeling is then considered and the transport equations for the Reynolds stresses and for the dissipation rate of the turbulence kinetic energy are solved on the basis of the Narrow Channel data. The comparison of the distributions of the various terms in the transport equations with published full channel DNS data confirms that, although the NC assumption substantially reduces the computational cost of the simulations, it does not affect the accuracy of the numerical predictions. Finally, as an example of the use that can be done of the numerical tool, an algebraic stress model and a one-equation model for the dissipation rate tensor for low Reynolds number flows are considered, and the modeled quantities are compared with their directly computed counterparts. DIRECT SIMULATION OF TURBULENT FLOW IN A SQUARE DUCT: REYNOLDS-STRESS BUDGETS

Asmund Huser, Sedat Biringen (Colorado Univ., Boulder, CO.), and Ferhat F. Hatay (Colorado Univ., Boulder, CO.) *In* AGARD, Application of Direct and Large Eddy Simulation to Transition and Turbulence Dec. 1994 12 p Sponsored by Fulbright Foundation, Norwegian Space Agency, and Royal Norwegian Council for Scientific and Industrial Research (For primary document see N95-21061 06-34)
Copyright Avail: CASI HC A03/MF A04

The data base from a direct numerical simulation of turbulent flow in a square duct is used to calculate all the terms in the Reynolds stress transport equations. The simulation of this complex turbulent flow was performed at a Reynolds number of 600 based on the friction velocity and the duct width. The distributions of the Reynolds stress budget terms along the wall bisector show similar dynamics to wall-bounded turbulent flows with one inhomogeneous direction. Budget terms in the vicinity of the corner demonstrate how transport and redistribution of energy and shear stresses between the Reynolds stress components takes place, promoting the turbulence characteristics of secondary flows of the second kind. The redistribution of energy by pressure velocity correlations can be explained by the low pressures at the cores of streamwise vortices. The data base is also used to evaluate a nonlinear turbulence model in its ability to accommodate the anisotropy of the Reynolds stress tensor in this flow. This anisotropy is known to be entirely responsible for the formation of the secondary flow in noncircular ducts and cannot be captured by linear models. Author

The present contribution reviews some of the recent progress obtained at our group in the direct numerical simulation (DNS) of compressible boundary layer transition. Elements of the different simulation approaches and numerical techniques employed are surveyed. Temporal and spatial simulations, as well as comparisons with results obtained from Parabolized Stability Equations, are discussed. DNS results are given for flat plate boundary layers in the Mach number range 1.6 to 4.5. A temporal DNS at Mach 4.5 has been continued through breakdown all the way to the turbulent stage. In addition results obtained with a recently developed extended temporal DNS approach are presented, which takes into account some nonparallel effects of a growing boundary layer. Results from this approach are quite close to those of spatial DNS, while preserving the efficiency of the temporal DNS. Author

SIMULATION OF LARGE SCALE TRANSITIONAL FLOWS [SIMULATION DES GRANDES ECHELLES D'ECOULEMENTS TRANSITIONNELS]

P. Comte, F. Ducros, J. Silvestrini, E. David, E. Lamballais, O. Metais, and M. Lesieur *In* AGARD, Application of Direct and Large Eddy Simulation to Transition and Turbulence Dec. 1994 12 p In FRENCH (For primary document see N95-21061 06-34)
Copyright Avail: CASI HC A03/MF A04

Two new subgrid-scale models of turbulence are proposed on the basis of a 2nd-order velocity structure function model developed by Metais and Lesieur. They result from two different approaches aimed at preventing fluctuations at large scales from bringing about turbulent viscosity. Simulations of boundary layers at Mach 0.5 are presented showing that these two models make it possible to simulate the transition to a turbulent regime developed at moderate computational costs in appreciably different configurations (adiabatic plate and strongly heated dihedral). Vorticity transport concepts are applied to large eddy simulation (LES) techniques in two different contexts. In the first example, the LES equations of motion are reformulated by applying a spatial filter to the rotational rather than the momentum form of the Navier-Stokes equation, leading to the introduction of a subgrid-scale (SGS) vorticity flux tensor. A model originally developed using ensemble averaging is proposed and tested locally and instantaneously using simulations of full channel flow and a minimal channel calculation. The modeled and exact vorticity fluxes are found to generally agree, even for vorticity flux terms which are only present locally and instantaneously. The development of a vorticity transport based wall treatment using a deterministic vortex element approach is also outlined. Initial tests comparing the results of this approach to the zero pressure gradient and stagnation point boundary layer are compared to the Blasius and Falkner-Skan solutions and found to be in good agreement. MODELLING ANISOTROPY AND BACKSCATTER EFFECTS IN THE SUBGRID SCALE STRESS TENSOR

T. Goutorbe and D. Laurence (Electricite de France, Chatou, France.) *In* AGARD, Application of Direct and Large Eddy Simulation to Transition and Turbulence Dec. 1994 7 p (For primary document see N95-21061 06-34)
Copyright Avail: CASI HC A02/MF A04

A new Subgrid scale (SGS) model used for Large-Eddy Simulation (LES) is developed by extending the scale-similarity hypothesis. Here a conventional Reynolds averaging is used instead of a test filter, resulting using the resolved (large scale) part of the Reynolds stress tensor. This resolved Reynolds stress (RRS) model, without any eddy viscosity assumption, is shown to properly reproduce the drain and backscatter partition of energy exchange between resolved and subgrid scales (for a channel flow at moderate Reynolds numbers). After assessing these properties by a priori tests (filtering DNS results), LES computations are carried out, determining the model constants by an analytical approach and a dynamic approach. In both cases, backscatter effects can lead to instabilities which are finally cured by introducing a transport equation for the SGS energy. This is felt necessary because when backscatter occurs, both SGS production and Kolmogorov dissipation are negative, so SGS energy must vanish, thus ending backscatter. Only a transport equation for the SGS energy can account for this energy conservation principle which is violated by dynamic approaches, that impose an average procedure. Slight discrepancies appear in the buffer layer which may be attributed to the insufficient resolution of streak structures in the spanwise direction. Thus, an adaptation for the buffer-layer appears to be the last obstacle to construct a model accounting for the most important physical properties required for SGS modeling and applicable for practical applications at high Reynolds numbers. In this paper we report simulations of low to moderate Reynolds number turbulent pipe flow, obtained using a 3-D spectral code. Here we describe features of flows at Reynolds numbers Re = 2500 and 4000 and compare with available data. It is noted that simulations with periodic inflow/outflow boundary conditions do not reproduce the turbulent puff and slug flows found in spatially evolving transitional flows. The goal is to coordinate the use of this code with the currently performed SuperPipe experiments now underway at Princeton University. Author

SIMULATIONS OF BYPASS TRANSITION FOR SPATIALLY EVOLVING DISTURBANCES

A. Lundbladh, P. J. Schmid (Washington Univ., Seattle, WA.), S. Berlin (Royal Inst. of Tech., Stockholm, Sweden.), and D. S. Henningson *In* AGARD, Application of Direct and Large Eddy Simulation to Transition and Turbulence Dec. 1994 13 p Sponsored by NASA. Langley Research Center (For primary document see N95-21061 06-34)
Copyright Avail: CASI HC A03/MF A04

The spatial evolution of disturbances in plane Poiseuille flow and zero pressure gradient boundary layer flow is considered. For disturbances governed by the linearized equations, potential for significant transient growth of the amplitude is demonstrated. The maximum amplification occurs for disturbances with zero or near zero frequencies. Spatial numerical simulations of the transition scenario involving a pair of oblique waves has been conducted for both flows. A fully spectral solver using a simple but efficient fringe region technique allowed the flows to be computed with high resolution into the fully turbulent domain. A modal decomposition of the simulation results indicates that non-linear excitation of the transient growth is responsible for the rapid emergence of low-frequency structures. Physically, this corresponds to streaky flow structures, as seen from the results of a numerical amplitude expansion. Thus, this spatial transition scenario has been found to be similar to the corresponding temporal one. In the boundary layer simulations the streaks are seen to break down from what appears to be a secondary instability. Author

DIRECT NUMERICAL DETERMINATION OF THE MINIMUM BYPASS REYNOLDS NUMBER IN BOUNDARY LAYERS

Roque Corral and Javier Jimenez *In* AGARD, Application of Direct and Large Eddy Simulation to Transition and Turbulence Dec. 1994 10 p Sponsored by ESA (For primary document see N95-21061 06-34)
Copyright Avail: CASI HC A02/MF A04

It is argued that bypass transition on a flat plate can be interpreted as a consequence of the subcritical nature of the instability of the boundary layer, and that the minimum bypass Reynolds number should coincide with the one at which the turbulent layer relaminarizes spontaneously. This threshold is found by direct numerical simulation of a spatially periodic turbulent layer in which spatial growth is modeled by a linear normal velocity. The computed mean profiles and integral properties agree well with experimental results at the higher Reynolds numbers, but diverge from them at the lower ones. While experiments turn away from the turbulent correlations below Re(sub theta) approx. equals 300 - 500, the computations follow them until relaminarizing abruptly at Re(sub theta) approx. equals 200. The simulations use relatively small periodic computational boxes, holding only a few boundary layer thickness, and it is argued that this provides enough feedback to prevent the transitional effects observed in experiments and to result in an absolute relaminarization threshold. The Reynolds number obtained in this way agrees with the onset of bypass transition in experiments with very high free stream turbulence levels, or with strong roughness tripping. Author

A FLAMELET MODEL FOR TURBULENT UNPREMIXED COMBUSTION

c25

V. R. Kuznetsov *In* AGARD, Application of Direct and Large Eddy Simulation to Transition and Turbulence Dec. 1994 10 p (For primary document see N95-21061 06-34)
Copyright Avail: CASI HC A02/MF A04

Combustion theory is an applied science which is syntheses of several fundamental theories such as chemistry, heat and mass transfer theory, hydrodynamics, turbulence, etc. Now the knowledge of these theories is adequate to make calculations for practical purposes. However some difficulties still remain unresolved. The most important one is associated with the steep dependence of chemistry on temperature. As a result chemistry is confined to very thin zones (flamelets). Hence very large memory and speed of computers are needed to resolve flamelets in DNS. This difficulty is aggravated by the large number of intermediate species. The use of turbulence closures does not help since one has to assume that eddy diffusivities of reacting species and their pdf's (which are needed to average chemistry rates) are the same as that of conserved scalar. There are several examples indicating that these assumptions may lead to significant errors. Therefore there is a need to develop some new approach. Author

DIRECT NUMERICAL SIMULATION FOR PREMIXED TURBULENT COMBUSTION MODELLING c25

R. S. Cant *In* AGARD, Application of Direct and Large Eddy Simulation to Transition and Turbulence Dec. 1994 13 p Sponsored by Stanford Univ., Shell Research Ltd., and the UK Science and Engineering Research Council (For primary document see N95-21061 06-34)
Copyright Avail: CASI HC A03/MF A04

Recent advances in computer power have made it feasible to carry out Direct Numerical Simulation (DNS) of fundamental test problems in turbulent combustion. Nevertheless the requirements in terms of numerical grid resolution remain very severe and engineering computations will remain beyond the reach of DNS for some time to come. Thus there is an undiminished role for statistical modeling using traditional moment-closure techniques and DNS can be used to provide fundamental data in support of such modeling. The present paper describes a specific example of the use of DNS results to improve the quality of a well-established model of premixed turbulent combustion. A brief outline of the model formulation is given, followed by a short description of the DNS and post-processing techniques employed. Some results of immediate utility are presented in order to illustrate the usefulness of the approach, and the parameterization of some further data is discussed in detail. The significance of the main improvements to the modeling is indicated and some remaining limitations are discussed. The prospects for future model refinement by improved DNS are examined and found to be excellent. Author

Results from a direct numerical simulation of turbulent mixing layer are presented. The flow evolves without shear and the mixing mechanisms associated with the turbulence are isolated. In the first set of simulations the turbulent mixing layer decays as energy is exchanged between the layers. In the second set, a forced mixing layer is simulated by continuously supplying energy to the higher energy side to maintain a stationary kinetic energy profile. Reynolds numbers based on the Taylor microscale of 28 and 38 are obtained in the decaying and forced simulations, respectively. The intermittency of the mixing layer is quantified by calculating the skewness and kurtosis of the velocity fields: results compare well with the shearless mixing layer experiments. Eddies of size of the integral scale (k(exp 3/2)/epsilon) penetrate the mixing layer intermittently, transporting energy and governing the growth rate. The scalar dissipation rate, a measure of the mixing, peaks in the mixing layer. The triple correlation models are applied to the inhomogeneous mixing layer and evaluated. The isotropic models tend to underpredict these correlations by as much as 60 percent while the more complicated anisotropic models are shown to be significantly more accurate. Both models for the pressure strain tensor are also shown to predict values that are incorrect by as much as 50 percent. Author

Direct simulations of two time-developing turbulent wakes have been performed. Initial conditions for the simulations were obtained from two realizations of a direct simulation of a turbulent boundary layer at momentum thickness Reynolds number 670. In addition, extra two-dimensional disturbances were added in one of the cases to mimic two-dimensional forcing. The unforced wake is allowed to evolve long enough to attain self-similarity. The mass-flux Reynolds number (equivalent to the momentum thickness Reynolds number in spatially developing wakes) is 2000, which is high enough for a short kappa(exp -5/3) range to be evident in the streamwise one-dimensional velocity spectrum. Several turbulence statistics have been computed by averaging in space and over the self-similar period in time. The growth rate in the unforced flow is low compared to experiments, but when this growth-rate difference is accounted for, the statistics of the unforced case are in reasonable agreement with experiments. However, the forced case is significantly different. The growth rate, turbulence Reynolds number, and turbulence intensities are as much as ten times larger in the forced case. In addition, the forced flow exhibits large-scale structures similar to those observed in transitional wakes, while the unforced flow does not. Author

A set of direct numerical simulations of temporally evolving incompressible plane wakes started from a variety of initial conditions have been performed. The intent is to explore the effect of initial conditions on the development of three dimensionality. It was found that the existence of an oblique disturbance at a streamwise wavelength equal to the two-dimensional subharmonic wavelength plays a very important role in the development of the wake. The Reynolds number and the presence or absence of longer wavelength disturbances were also found to be important at late times in the development of the flow. Disturbance phase was found to have an effect on the details of the structure of the wake, but has relatively little effect on the wake growth. Author

Direct numerical simulation of the tridimensional wake developing downstream from a NACA 0012 wing has been performed using the spectral element code NEKTON. The onset of instability in the wake of an infinite NACA 0012 wing is investigated. The first bifurcation is studied in a two dimensional configuration with a mesh obtained using the numerical experience with a two dimensional unstable cylinder wake. The second bifurcation accompanied by the onset of three-dimensionality is simulated on a three dimensional spectral element mesh obtained by extending the two-dimensional mesh spanwise. The onset of three-dimensionality is characterized by a deformation of the downstream and transverse velocity profiles in the spanwise direction and by the onset of an oscillating spanwise velocity. The critical Reynolds numbers are estimated for both bifurcations. The second bifurcation is shown to be characterized by a period doubling, i.e., the Strouhal frequency of the spanwise velocity is rather precisely equal to half the frequency of the transverse velocity oscillations. This result is in agreement with the numerical results of Karniadakis and Triantafyllou obtained for an infinite circular cylinder and confirms indirectly the experimental results of Williams-Stuber and Gharib showing that to obtain a Ruelle and Takens scenario in a wake, an external forcing is needed. Furthermore, simulations in a geometrically three-dimensional configuration of a finite wing are performed. The development of the tip vortex of a finite wing is investigated. Comparisons are made with available experimental results performed at low Reynolds numbers. The structure of the three dimensional flow is found to be in good agreement with experiments. The simulations are carried out at supercritical Reynolds numbers at which the wake is unstable. The wake oscillations and tip vortex oscillations are evidenced and shown to be characterized by roughly the same Strouhal frequency although the computations could not be pushed until relaxation of transients. The flowfield of an impinging jet is investigated numerically by means of the LES technique. The numerical scheme uses a high order upwind biased formulation for the advective transport. A localized dynamic evaluation of the Smagorinsky constant is employed to avoid an empirical tuning of this value. A critical problem is the formulation of open boundary conditions. The set of boundary conditions presented here allows both the entrainment of fluid into the computational domain as well as the exit of the large vortical structures typical for this flow problem. Direct and Large Eddy simulations of temporal evolving round jets at low Reynolds numbers have been performed by a second-order finite difference scheme in cylindrical coordinates. The simulations have shown the formation of longitudinal structures whose number increases with the Reynolds number. The role of these structures in the spreading of the jet and in the creation of small scales has been analyzed. LES models (Smagorinsky and dynamic models) permit to have satisfactory results with coarse grids. Author

The three-dimensional time evolution of a highly symmetrical vortex array is simulated using a Fourier pseudospectral method for Re = 1/nu = 2000 with an effective resolution of 1024(exp 3) collocation points (k(sub max) = 340). It is found that before the peak enstrophy is reached, there is a short stage when the local quantities increase sharply. The velocity derivative skewness and flatness values reach to 0.9 and 80 respectively. It is also found that during this interval, 6 vortex dipoles (at the origin) and 3 dipoles (at the pi/2 corner) collapse towards two separate vorticity null points. The coherent vortices break up afterwards followed by sharp decrease in local quantities possibly due to dissipation. The singularity analysis shows that maximum vorticity scales as (T - T(sub c))(exp -1) shortly before the break up. The temporal evolution of the width of the analyticity strip shows that delta approaches zero but reaches a minimum positive value and starts to increase. This suggests that the solution remains uniformly analytic similar to the viscous Burgers equation. Author

The objective of this paper is to review our efforts in spatial direct numerical simulations for modeling leading-edge receptivity to freestream sound and vorticity. These results begin to provide the link between the freestream and the initial boundary-layer response and can provide the upstream conditions for further simulations marching through the transition process toward turbulence. Direct Numerical Simulation is applied to a variety of small perturbations developing in a three-dimensional boundary layer. The basic flow is independent of the spanwise coordinate but incorporates a favorable and an adverse pressure gradient in the chordwise direction, similar to the leading-edge region of a swept wing. The edge velocity is analytically defined. Both Cross-Flow and Tollmien-Schlichting modes are amplified. Results focus on questions that are often open in three-dimensional transition-predictions codes, particularly 'e(exp N)' type codes. They include: non-parallel effects; choice of wave-vector; choice of propagation velocity and direction; and the effect of broad spectra, in either space direction and/or time. For this we survey a range of perturbations from pure waves to wave packets; the latter result from initial perturbations that are local in both space and time, and are arguably the richest type of disturbance. Quantitative results are offered for the validation of stability codes, and some are compared with Orr-Sommerfeld results. Author

ON SUBCRITICAL INSTABILITY OF THE ATTACHMENT LINE BOUNDARY LAYER

Vassilios Theofilis *In* AGARD, Application of Direct and Large Eddy Simulation to Transition and Turbulence Dec. 1994 8 p (For primary document see N95-21061 06-34)

Copyright Avail: CASI HC A02/MF A04

Subcritical instability in the two-dimensional incompressible attachment-line boundary layer remains a topic of debate, after the apparently contradictory results of Hall and Malik (1986) on one hand and Spalart (1988) and Jimenez et al. (1990) on the other. Direct Numerical Simulation (DNS) results are presented, aiming at addressing this question. Extensive numerical experimentation has been performed and all results obtained suggest that the two-dimensional model equations describing leading edge boundary layer (LEBL) flow doe not support solutions growing subcritically in Reynolds number, although the nonlinear neutral loop is seen to bifurcate from its linear counterpart in a manner consistent with the predictions of the theory of Hall and Malik (1986). Nonlinear neutral loops have been obtained suggesting that the two-dimensional model LEBL flow is similar to the classical Blasius boundary layer in terms of the location, in parameter space, of the experimentally observed naturally occurring instability waves. Laminar-turbulent breakdown of a strongly decelerated Falkner-Skan-type boundary layer (Hartree-Parameter beta(sub H)=-0.18) is investigated by direct numerical simulations using the complete Navier-Stokes equations for three-dimensional incompressible flows. The numerical method is based on the so-called spatial model, and allows for simulations of spatially evolving three-dimensional disturbance waves in a two-dimensional growing boundary layer. Transition is initiated by 2-D and a pair of oblique 3-D waves, both with small amplitudes, excited periodically within a narrow disturbance strip at the plate surface. Their streamwise (linear and subsequent nonlinear) evolution resulting in the fundamental breakdown of laminar flow is simulated with high spatial resolution. It is observed that the fundamental breakdown process under adverse pressure gradient is dramatically more complex than the well-known K-breakdown in the Blasius flow: In addition to the (upper) high-shear layer on top of the lambda-vortex, a (lower) characteristic high-shear layer is formed simultaneously in between neighboring lambda-vortices. This shear layer, induced by a secondary vortex system close to the wall, precipitates ultimate breakdown to turbulence. Finally, some results of preliminary studies on the effect of suction on boundary-layer transition are presented that demonstrate the great potential of spatial direct numerical simulations for applied transition research in flows of practical interest. NAVIER-STOKES SIMULATIONS OF THE EFFECTS OF SUCTION HOLES ON A FLAT PLATE BOUNDARY LAYER

Hubert L. Meitz and Hermann F. Fasel *In* AGARD, Application of Direct and Large Eddy Simulation to Transition and Turbulence Dec. 1994 10 p (For primary document see N95-21061 06-34)
(Grant NAG1-1422)
Copyright Avail: CASI HC A02/MF A04

Direct numerical simulations (DNS) of the Navier-Stokes equations are employed to explore the effects of suction holes on transition in a laminar flat plate boundary layer. The Navier-Stokes equations are cast in vorticity-velocity form. Periodicity is imposed in spanwise direction; all other spatial derivatives are discretized with fourth order compact differences. An explicit fourth order Runge-Kutta scheme is employed for the time-integration of the vorticity transport equations. Suction is applied through a row of holes aligned in spanwise direction. For low suction strengths, each hole generates a pair of stable streamwise vortices. When the suction strength exceeds a critical value, the vortices become unstable. For high suction strengths, vortex shedding occurs right at the suction holes. Our numerical findings agree well with experimental observations. Author

DIRECT NUMERICAL SIMULATION OF 2-D AND 3-D INSTABILITY WAVES IN A LAMINAR SEPARATION BUBBLE

Ulrich Rist and Ulrich Maucher *In* AGARD, Application of Direct and Large Eddy Simulation to Transition and Turbulence Dec. 1994 7 p (For primary document see N95-21061 06-34)
(Contract DFG-Ri-680/1-1)
Copyright Avail: CASI HC A02/MF A04

Direct Numerical Simulations of a laminar separation bubble are presented, where the bubble is generated by prescribing a locally decelerated free-stream velocity along a flat-plate. Controlled disturbances are introduced into the flow field upstream of the bubble by suction and blowing through the wall in order to study the linear and nonlinear stability characteristics of the flow. A number of generic cases with different two-dimensional (2-D) and three-dimensional (3-D) initial disturbance amplitudes are investigated: (1) a linear case; (2) a case subject to secondary instability (strong amplification of 3-D disturbances by resonance with a large amplitude 2-D wave); (3) a 3-D nonlinear case (interaction of two oblique waves); and (4) a nonlinear case combining the interaction of two oblique waves with a 2-D wave. Good quantitative agreement of the numerical results with (local) linear stability theory is observed throughout case (1) and for the initial disturbance development of the priming waves in the other cases despite the nonparallel base flow. For the nonlinear disturbance development development, however, unexpected results are obtained: Secondary instability is hard to distinguish from primary instability and apparently breaks down as soon as the priming 2-D disturbances saturate. However, the nonlinear mechanism identified in cases (3) and (4), is obviously much more likely to produce large amplitude 3-D disturbances necessary for the generation of a transitional laminar separation bubble. The mechanism leads to a nonlinearly saturated regime with reasonably turbulent mean-flow characteristics as well as longitudinal vortices in the reattachment zone. Author

INVESTIGATION OF SHEAR LAYER TRANSITION USING VARIOUS TURBULENCE MODELS

J. K. Kaldellis and G. A. Georgantopoulos *In* AGARD, Application of Direct and Large Eddy Simulation to Transition and Turbulence Dec. 1994 11 p (For primary document see N95-21061 06-34)
Copyright Avail: CASI HC A03/MF A04

The accurate prediction of shear layer transition plays an important role in the performance amelioration of modern aero-mechanical devices, since transitional shear layers are frequently observed on axial turbomachine blades and other low Reynolds number airfoils. In the present work some of the most famous existing turbulence models are used in order to analyze a large variety of well documented experimental transitional shear flows. Particular attention is paid to the estimation of the transition length and to the calculation of loss evolution inside the transition area. Finally interesting conclusions of the proposed analysis are summarized in the last part of the paper, where the behavior of several transitional blade shear layers is examined, applying the most reliable of the above tested turbulence models. DNS OF TURBULENT FLOW IN A DRIVEN CAVITY AND THEIR ANALYSIS USING PROPER ORTHOGONAL DECOMPOSITION

W. Cazemier, R. W. C. P. Verstappen, and A. E. P. Veldman *In* AGARD, Application of Direct and Large Eddy Simulation to Transition and Turbulence Dec. 1994 11 p (For primary document see N95-21061 06-34)
Copyright Avail: CASI HC A03/MF A04

Direct Numerical Simulation (DNS) of 2D and 3D lid-driven cavity flows have been performed. The results have been analyzed using Proper Orthogonal Decomposition (POD). POD has been applied to a 2D driven cavity at Reynolds number 22,000 and to a 3D at Re = 10,000. The POD-basis-functions have been computed using the so-called 'snapshot' method of Sirovich. The 2D basisfunctions are used for a Galerkin projection of the Navier-Stokes equations. This results in a relatively low (20 to 80) dimensional dynamical behavior, that shows (almost) the same dynamical behavior, in short and long term, as the DNS. Moreover, if the Reynolds number is set to 11,000, the 80-dimensional dynamical system has (almost) the same periodic solution as the 2D Navier-Stokes equations have at Re = 11,000. Author

Direct Simulations involve huge amounts of time dependent data and are expensive to run fully even on supercomputers. A thousand hours of CRAY to obtain valid results is in the order of things. Such costs can be significantly reduced by MIMD machines. To be able to analyze the computed results many and various visualization techniques are also essential. This paper presents work that was done at ONERA to parallelize a Navier-Stokes solver PEGASE and development of an interactive visualization tool at CIRA applied to numerical turbulent flow fields generated by the solver. This work was partly achieved within the framework of the European RACE/PAGEIN project which was aimed at demonstrating the feasibility of Direct Numerical Simulation techniques for future industrial developments, implying modern supercomputer technology, high performance computing networking and massive data transfers between vector and/or parallel supercomputers. The first part of this paper presents the essential characteristics of version 1.0 of PEGASE implemented on a vector machine, the second part describes modifications in algorithms and coding in order to implement it efficiently on the IPSC860 and on a PARAGON. Numerical results and comparisons in costs between the three machines are given. The third part describes the graphics post-processing developed at CIRA. Author

APPLICATION OF ROE'S FLUX-DIFFERENCE SPLITTING FOR KAPPA-EPSILON TURBULENCE MODEL

T. Silkonen 3 May 1994 37 p
(PB95-127718; SER-A-94-A15) Avail: Issuing Activity (National Technical Information Service (NTIS))

In the paper Roe's flux-difference splitting is applied for the solution of Reynolds-averaged Navier-Stokes equations. Turbulence is modeled using a low-Reynolds number form of the K-epsilon turbulence model. The coupling between the turbulence kinetic energy equation and the inviscid part of the flow equations is taken into account. The equations are solved with a DDADI-factorized implicit time integration method. A multigrid algorithm is used to accelerate the convergence. To improve the stability some modifications are needed in comparison with the application of an algebraic turbulence model. The developed method is applied to three different test cases. These cases show the efficiency of the algorithm, but the results are only marginally better than those obtained with algebraic models. NTIS

COMPUTATION OF TRANSONIC FLOW ON COMPOSITE OVERLAPPING GRIDS IN 2 D
Brodd Leif Andersson Apr. 1994 134 p
(ISSN 0347-3694)
(PB95-131348; FOA-C-20972-2.5) Avail: CASI HC A07/MF A02

We study the composite overlapping grid technique by applying it to two cases of transonic flow past an airfoil in two dimensions. A second order accurate explicit time marching finite difference scheme for the pseudo-unsteady Euler equations together with first order nonconservative interpolation at the component grid interfaces has been used. The numerical results indicate that the technique of overlapping grids is very useful if the decomposition of the domain is made carefully. A substantial improvement of the resolution in particular parts of the domain is easily obtained by the use of refined subgrids. NTIS

Nonlinear evolution of Goertler and crossflow vortices is investigated. The associated secondary instabilities of these streamwise vortices are also studied. The Goertler vortex is found to be subject to two types of secondary modes: a sinuous mode and a varicose mode similar to that observed in the experiments. The growth rate of the sinuous mode is higher initially but the varicose mode becomes more unstable in the downstream. It is also found that crossflow vortices are subject to a high frequency secondary instability prior to breakdown, as found in experiments performed on swept wings. In agreement with the experiments, our calculations show that the frequency of this secondary instability, which resides on top of the crossflow vortex, is an order of magnitude higher than the frequency of the most amplified traveling crossflow disturbances. The interaction of stationary and traveling disturbances is also considered. These studies have been carried out by using parabolized stability equations (PSE) and a two-dimensional (2D) eigenvalue approach. The mathematical nature of PSE approximation is also discussed. Vector field rendering is difficult in 3D because the vector icons overlap and hide each other. We propose four different techniques for visualizing vector fields only near surfaces. The first uses motion blurred particles in a thickened region around the surface. The second uses a voxel grid to contain integral curves of the vector field. The third uses many antialiased lines through the surface, and the fourth uses hairs sprouting from the surface and then bending in the direction of the vector field. All the methods use the graphics pipeline, allowing real time rotation and interaction, and the first two methods can animate the texture to move in the flow determined by the velocity field. DOE

(NASA-TM-4577; L-17162; NAS 1.15:4577) Avail: CASI HC A03/MF A01

The boundary layer receptivity to free-stream acoustic waves in the presence of localized surface disturbances is studied for the case of incompressible Falkner-Skan flows with adverse pressure gradients. These boundary layers are unstable to both viscous and inviscid (i.e., inflectional) modes, and the finite Reynolds number extension of the Goldstein-Ruban theory provides a convenient method to compare the efficiency of the localized receptivity processes in these two cases. The value of the efficiency function related to the receptivity caused by localized distortions in surface geometry is relatively insensitive to the type of instability mechanism, provided that the same reference length scale is used to normalize the efficiency function for each type of instability. In contrast, when the receptivity is induced by variations in wall suction velocity or in wall admittance distribution, the magnitudes of the related efficiency functions, as well as the resulting coupling coefficients, are smaller for inflectional (i.e., Rayleigh) modes than for the viscous Tollmien-Schlichting waves. The reduced levels of receptivity can be attributed mainly to the shorter wavelengths and higher frequencies of the inflectional modes. Because the most critical band of frequencies shifts toward higher values, the overall efficiency of the wall suction- and the wall admittance-induced receptivity decreases with an increase in the adverse pressure gradient. TRANSIENT BEHAVIOUR AND STABILITY POINTS OF THE POISEUILLE FLOW OF A KBKZ-FLUID
A. C. T. Aarts and A. A. F. vandeVen Jun. 1994 29 p
(ISSN 0926-4507)
(PB95-132064; RANA-94-10) Avail: CASI HC A03/MF A01

The Poiseuille flow of a Kaye-Bernstein-Kearsly-Zapas (KBKZ) fluid, being a nonlinear viscoelastic model for a polymeric fluid, is studied. The flow starts from rest and especially the transient phase of the flow is considered. It is shown that under certain conditions the steady flow equation has three different equilibrium points. The stability of these points is investigated. It is proved that two points are stable, whereas the remaining one is unstable, leading to several peculiar phenomena such as discontinuities in the velocity gradient near the wall of the pipe ('spurt') and hysteresis. Our theoretical results are confirmed by numerical calculations of the velocity gradient. NTIS

SUPERSONIC LAMINAR FLOW CONTROL RESEARCH Semiannual Report No. 2, Jul. - Dec. 1994

Ching F. Lo Dec. 1994 65 p
(Grant NAG2-881)
(NASA-CR-196049; NAS 1.26:196049) Avail: CASI HC A04/MF A01

The objective of the research is to understand supersonic laminar flow stability, transition, and active control. Some prediction techniques will be developed or modified to analyze laminar flow stability. The effects of supersonic laminar flow with distributed heating and cooling on active control will be studied. The primary tasks of the research applying to the NASA/Ames Proof of Concept (POC) Supersonic Wind Tunnel and Laminar Flow Supersonic Wind Tunnel (LFSWT) nozzle design with laminar flow control are as follows: (1) predictions of supersonic laminar boundary layer stability and transition, (2) effects of wall heating and cooling for supersonic laminar flow control, and (3) performance evaluation of POC and LFSWT nozzles design with wall heating and cooling effects applying at different locations and various length. A MIXED TIME INTEGRATION METHOD FOR LARGE SCALE ACOUSTIC FLUID-STRUCTURE INTERACTION
M. A. Christon, S. J. Wineman, G. L. Goudreau, and J. D. Foch 18 Jul. 1994 14 p Presented at the American Society of Mechanical Engineers' Winter Annual Meeting, Chicago, IL, 9-11 Nov. 1994
(Contract W-7405-eng-48)
(DE94-018327; UCRL-JC-117820; CONF-941142-20) Avail: CASI HC A03/MF A01

The transient, coupled, interaction of sound with structures is a process in which an acoustic fluid surrounding an elastic body contributes to the effective inertia and elasticity of the body. Conversely, the presence of an elastic body in an acoustic medium influences the behavior of propagating disturbances. This paper details the application of a mixed explicit-implicit time integration algorithm to the fully coupled acoustic fluid-structure interaction problem. Based upon a dispersion analysis of the semi-discrete wave equation a second-order, explicit scheme for solving the wave equation is developed. The combination of a highly vectorized, explicit, acoustic fluid solver with an implicit structural code for linear elastodynamics has resulted in a simulation tool, PING, for acoustic fluid-structure interaction. PING's execution rates range from 1 micro s/Element/(delta)t for rigid scattering to 10 micro s/Element/(delta)t for fully coupled problems. Several examples of PING's application to 3-D problems serve in part to validate the code, and also to demonstrate the capability to treat complex geometry, acoustic fluid-structure problems which require high resolution meshes. INSTABILITIES IN NATURAL-CONVECTION FLOWS IN CAVITIES Ph.D. Thesis [INSTABILITEITEN IN NATUURLIJKE CONVECTIESTROMINGEN IN GESLOTEN RUIMTES]
Roger Joseph Anna Janssen 9 May 1994 188 p Sponsored by the Stichting voor Fundamenteel Onderzoek der Materie
(PB95-107975) Avail: CASI HC A09/MF A02

In the thesis, a study of instabilities occurring in a natural-convection flow is described. Natural-convection flows arise from density differences in a fluid. These density differences, under the influence of the earth's gravity field, result in a buoyant force which causes the heavier fluid particles to descend and the lighter fluid particles to ascend and which thus drives the resulting flow. The adjective natural is used to distinguish these flows from forced-convection flows which are driven by pressure differences. The density differences occurring in natural-convection flows may have their origin in a number of different physical phenomena; they may result from temperature differences, from differences in the concentration of chemical species in the fluid and from the presence of multiple phases in the fluid. In the present study, however, only flows in which the density differences are caused by temperature differences are considered. NTIS

FLOW AND HEAT TRANSFER SIMULATION IN A FLASH SMELTING FURNACE
T. Ahokainen, A. Jokilaakso, O. Teppo, and Y. Yang 1994 34 p
(PB95-108197; TKK-V-B94) Avail: Issuing Activity (National Technical Information Service (NTIS))

Fluid flow and heat transfer phenomena taking place in an industrial Outokumpu type flash smelting furnace were simulated with CFD software CFD2000 1.0 and PHOENICS 1.6.6. The computational domains and grids are basically the same as described in earlier reports. However, some changes and simplifications are made to the grids, especially in the reaction shaft model. All the two-phase simulations presented in the report are cold and isothermal, where the particles exchange only momentum with the gas phase. As a first attempt, combustion of gaseous sulphur with oxygen was used to represent the heat release from the copper concentrate oxidation reactions. The results presented in the report are preliminary reflecting the different stages of the model development. NTIS

STABILITY OF PRESSURE AND VELOCITY COMPUTATIONS FOR HETEROGENEOUS RESERVOIRS
A. M. Bruaset and B. F. Nielsen 20 Apr. 1994 22 p
(PB95-110284; STF33-A94031) Avail: Issuing Activity (National Technical Information Service (NTIS))

This paper is concerned with the stability of self-adjoint second order elliptic problems with respect to perturbations of the involved coefficient functions. In particular, we study such behavior for the pressure equation related to incompressible or steady state flow in a heterogeneous reservoir. We establish analytical estimates on the changes in the pressure and velocity caused by mobility perturbations measured by suitable norms. This stability analysis is complemented by numerical experiments. NTIS

NUMERICAL INVESTIGATIONS OF LOW-DENSITY NOZZLE FLOW BY SOLVING THE BOLTZMANN EQUATION
Zheng-Tao Deng, Goang-Shin Liaw (Alabama A & M Univ., Huntsville, AL.), and Lynn Chen Chou (Alabama A & M Univ., Huntsville, AL.) 1995 6 p Presented at the 33rd Aerospace Science Meeting and Exhibit, Reno, NV, 9-12 Jan. 1995

(Grant NAG8-201)
(NASA-TM-110492; NAS 1.15:110492) Copyright Avail: CASI HC A02/MF A01

A two-dimensional finite-difference code to solve the BGK-Boltzmann equation has been developed. The solution procedure consists of three steps: (1) transforming the BGK-Boltzmann equation into two simultaneous partial differential equations by taking moments of the distribution function with respect to the molecular velocity u(sub z), with weighting factors 1 and u(sub z)(sup 2); (2) solving the transformed equations in the physical space based on the time-marching technique and the four-stage Runge-Kutta time integration, for a given discrete-ordinate. The Roe's second-order upwind difference scheme is used to discretize the convective terms and the collision terms are treated as source terms; and (3) using the newly calculated distribution functions at each point in the physical space to calculate the macroscopic flow parameters by the modified Gaussian quadrature formula. Repeating steps 2 and 3, the time-marching procedure stops when the convergent criteria is reached. A low-density nozzle flow field has been calculated by this newly developed code. The BGK Boltzmann solution and experimental data show excellent agreement. It demonstrated that numerical solutions of the BGK-Boltzmann equation are ready to be experimentally validated. Author

A NEW KRYLOV-SUBSPACE METHOD FOR SYMMETRIC INDEFINITE LINEAR SYSTEMS

R. W. Freund (Bell Telephone Labs., Inc., Murray Hill, NJ.) and N. M. Nachtigal Oct. 1994 16 p
(Contract DE-AC05-84OR-21400)
(DE95-001826; ORNL/TM-12754) Avail: CASI HC A03/MF A01

Many important applications involve the solution of large linear systems with symmetric, but indefinite coefficient matrices. For example, such systems arise in incompressible flow computations and as subproblems in optimization algorithms for linear and nonlinear programs. Existing Krylov-subspace iterations for symmetric indefinite systems, such as SYMMLQ and MINRES, require the use of symmetric positive definite preconditioners, which is a rather unnatural restriction when the matrix itself is highly indefinite with both many positive and many negative eigenvalues. In this note, the authors describe a new Krylov-subspace iteration for solving symmetric indefinite linear systems that can be combined with arbitrary symmetric preconditioners. The algorithm can be interpreted as a special case of the quasi-minimal residual method for general non-Hermitian linear systems, and like the latter, it produces iterates defined by a quasi-minimal residual property. The proposed method has the same work and storage requirements per iteration as SYMMLQ or MINRES, however, it usually converges in considerably fewer iterations. Results of numerical experiments are reported. DOE

SUPERCONDUCTING ELECTROMAGNETIC THRUSTER Patent

James C. Meng, inventor (to Navy) 2 Aug. 1994 15 p Filed 11 Feb. 1993
(AD-D016485; US-Patent-5,333,444; US-Patent-Appl-SN-016324; US-Patent-Class-60-221) Avail: US Patent and Trademark Office

An electromagnetic thruster for marine vehicles using a jet of water driven by the interaction of a mutually perpendicular intensified magnetic field and an intensified electric field is disclosed. The intensified magnetic field is produced by superconducting coils cooled by a coolant such as liquid helium. An intensified electric field is produced by passing high amperage current across the seawater jet. These interacting fields produce a Lorentz force perpendicular to mutually perpendicular electric and magnetic field vectors which is used to drive the seawater jet. In some embodiments, the force may also be used to draw water into the jet from the boundary layer flow around the vehicle thereby reducing boundary layer turbulence and associated radiated noise. THE VELOCITY AND VORTICITY FIELDS OF THE TURBULENT NEAR WAKE OF A CIRCULAR CYLINDER Final Report

James Wallace (Maryland Univ., College Park, MD.), Lawrence Ong (Maryland Univ., College Park, MD.), and Parviz Moin Jan. 1995 24 p
(Contract NCC2-5003)
(NASA-TM-110513; NAS 1.15:110513) Avail: CASI HC A03/MF A01

The purpose of this research is to provide a detailed experimental database of velocity and vorticity statistics in the very near wake (x/d less than 10) of a circular cylinder at Reynolds number of 3900. This study has determined that estimations of the streamwise velocity component in flow fields with large nonzero cross-stream components are not accurate. Similarly, X-wire measurements of the u and v velocity components in flows containing large w are also subject to the errors due to binormal cooling. Using the look-up table (LUT) technique, and by calibrating the X-wire probe used here to include the range of expected angles of attack (+/- 40 deg), accurate X-wire measurements of instantaneous u and v velocity components in the very near wake region of a circular cylinder has been accomplished. The approximate two-dimensionality of the present flow field was verified with four-wire probe measurements, and to some extent the spanwise correlation measurements with the multisensor rake. Hence, binormal cooling errors in the present X-wire measurements are small. Derived from text

HYBRID UPWIND SPLITTING (HUS) BY A FIELD-BY-FIELD DECOMPOSITION

Frederic Coquel and Meng-Sing Liou Jan. 1995 91 p
(Contract NCC3-233; RTOP 505-62-52)
(NASA-TM-106843; ICOMP-95-2; E-9408; NAS 1.15:106843) Avail: CASI HC A05/MF A01

We introduce and develop a new approach for upwind biasing: the hybrid upwind splitting (HUS) method. This original procedure is based on a suitable hybridization of current prominent flux vector splitting (FVS) and flux difference splitting (FDS) methods. The HUS method is designed to naturally combine the respective strengths of the above methods while excluding their main deficiencies. Specifically, the HUS strategy yields a family of upwind methods that exhibit the robustness of FVS schemes in the capture of nonlinear waves and the accuracy of some FDS schemes in the resolution of linear waves. We give a detailed construction of the HUS methods following a general and systematic procedure directly performed at the basic level of the field by field (i.e. waves) decomposition involved in FDS methods. For such a given decomposition, each field is endowed either with FVS or FDS numerical fluxes, depending on the nonlinear nature of the field under consideration. Such a design principle is made possible thanks to the introduction of a convenient formalism that provides us with a unified framework for upwind methods. The HUS methods we propose bring significant improvements over current methods in terms of accuracy and robustness. They yield entropy-satisfying approximate solutions as they are strongly supported in numerical experiments. Field by field hybrid numerical fluxes also achieve fairly simple and explicit expressions and hence require a computational effort between that of the FVS and FDS. Several numerical experiments ranging from stiff 1D shock-tube to high speed viscous flows problems are displayed, intending to illustrate the benefits of the present approach. We assess in particular the relevance of our HUS schemes to viscous flow calculations. Author

COMPUTATIONS OF UNSTEADY VISCOUS COMPRESSIBLE FLOWS USING ADAPTIVE MESH REFINEMENT IN CURVILINEAR BODY-FITTED GRID SYSTEMS

E. Steinthorsson, David Modiano, and Phillip Colella (California Univ., Berkeley, CA.) Aug. 1994 14 p Presented at the 25th Fluid Dynamics Conference, Colorado Springs, CO, 20-23 Jun. 1994; sponsored by AIAA
(Contract NCC3-233; RTOP 505-90-5K)
(NASA-TM-106704; ICOMP-94-17; E-9066; NAS 1.15:106704; AIAA Paper 94-2330) Avail: CASI HC A03/MF A01

A methodology for accurate and efficient simulation of unsteady, compressible flows is presented. The cornerstones of the methodology are a special discretization of the Navier-Stokes equations on structured body-fitted grid systems and an efficient solution-adaptive mesh refinement technique for structured grids. The discretization employs an explicit multidimensional upwind scheme for the inviscid fluxes and an implicit treatment of the viscous terms. The mesh refinement technique is based on the AMR algorithm of Berger and Colella. In this approach, cells on each level of refinement are organized into a small number of topologically rectangular blocks, each containing several thousand cells. The small number of blocks leads to small overhead in managing data, while their size and regular topology means that a high degree of optimization can be achieved on computers with vector processors. VORTEX ATOMS AND VORTONS Ph.D. Thesis

Alfons Johannes Quir Alkemade 5 Apr. 1994 223 p
(PB95-134599; ISBN-90-370-0103-3) Copyright Avail: Issuing Activity (National Technical Information Service (NTIS))

The thesis deals with two topics which are related to the concept of vorticity. Therefore, it consists of two parts. The 'vortex-atom-part' shows the development of a theory of matter, introduced by the English scientist Lord Kelvin in 1867, which would attract the attention of several 19th century scientists up to the beginning of our century. Kelvin's 'vortex atom theory' can be put into the context of several developments in 19th century physics, especially those with regard to theories of matter and the still developing theory of rotational flow or vorticity. The second part, the 'vorton-part', is an account of the theoretical foundation and the application to numerical simulations of the vorton method. This is one of the many vortex methods, applied nowadays to the (numerical) study of flow phenomena. Vortex methods are based on the fact that vortices play important roles in fluid flows and can be regarded as important applications of the knowledge on vortex motion which has been gathered in the past centuries and of the surging use of numerical techniques in fluid mechanics. The vorton method will be investigated by means of numerical simulation of several test cases. Most of these were already studied by the scientists who occupied themselves with the elaboration of the vortex atom model or who were just incited to research on vortex motion by this model. However, their investigations were largely hindered by mathematical difficulties. Today, the use of vortex methods as computational tools may provide more insight into the kinematics and dynamics of vortex structures. NTIS

STATE OF THE ART IN CFD PRE- AND POSTPROCESSING

B. E. Vembe and E. W. M. Hansen 9 Jun. 1994 50 p
(PB95-110391; STF15-A94004) Avail: Issuing Activity (National Technical Information Service (NTIS))

Computational fluid dynamics (CFD) is a generic name for a wide range of numerical techniques that are used for obtaining solutions to the governing equations of thermo-fluid dynamics with or without chemical reactions. The report presents to the state of the art in pre- and postprocessing for CFD codes, both commercial and in-house SINTEF-NTH codes. The objectives of advanced CFD systems are discussed and the techniques for pre- and postprocessing are reviewed. The user friendliness of CFD codes, in general, are highlighted. A common definition of a user friendly computer program is one that is easy to learn, efficient, easy to remember, and satisfactory to use. Most of today's commercial CFD codes could benefit from an enhanced interface. It is desirable to develop standard data formats for input and output of CFD codes and direct-manipulation user interfaces are desirable in CFD applications. Largest potential for improvements of CFD codes and for users is in geometry modeling and grid generation. NTIS

ELASTIC MICRO-FABRICATED SURFACE LAYER FOR REDUCING TURBULENCE AND DRAG ON AN OBJECT WHILE IT MOVES THROUGH A FLUID MEDIUM Patent

Promode R. Bandyopadhyay, inventor (to Navy) 13 Sep. 1994 8 p Filed 1 Jun. 1993
(AD-D016516; US-Patent-5,346,745; US-Patent-Appl-SN-069820; US-Patent-Class-428-156) Avail: US Patent and Trademark Office

A surface for use in connection with an object in relative motion through a fluid medium includes a plurality of surface elements arranged in rows on the surface, with surface elements of each row being arranged generally orthogonal to the direction of relative motion of the object in a medium. Each surface element includes means defining a cavity, the means including a bottom surface layer, sidewalls, and an upper lip supported along an upstream edge in a cantilevered manner and extending in a downstream direction over the cavity to define a gap permitting fluid communication between the medium and the cavity. The lip is flexible so as to facilitate deflection in response to differentials between pressure inside the cavity and outside the cavity. The cavities of the surface elements in each row are interconnected by means of passageways thereby to facilitate fluid communication therebetween. DTIC

ABSORBING BOUNDARY CONDITION FOR FLOATING TWO-DIMENSIONAL OBJECTS IN CURRENT AND WAVES

L. M. Sierevogel and A. J. Hermans 1994 17 p
(ISSN 0922-5641)
(PB95-132882) Copyright Avail: Issuing Activity (National Technical Information Service (NTIS))

In the paper a new absorbing boundary condition for floating two-dimensional objects in current and waves is studied. A numerical algorithm is developed, which computes the velocity potential in the physical time domain, using an artificial boundary to split the infinite fluid domain into a computational and residual part. In the residual part a special Green's function is developed. The condition on the artificial boundary is independent of the wave frequency, hence there is no restriction to harmonic waves. Because of the smaller computational domain and the independence of frequency the time to compute the hydrodynamic coefficients of floating objects will decrease. NTIS

THE MECHANISMS AND EFFECTS OFF THE PLANT-ACTIVATIONS OF CHEMICALS IN THE ENVIRONMENT Annual Report, 30 Apr. 1992 - 29 Sep. 1993

Michael J. Plewa 20 Dec. 1993 23 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Grant AF-AFOSR-0432-91)
(AD-A279388; AFOSR-94-0286TR) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Plants can activate promutagens into stable mutagens and these genotoxic agents may be hazardous to the environment and to the public health. Plant systems have been widely employed in classical and environmental mutagenesis. However, the environmental and human health impact of plants exposed to environmental xenobiotics were not well recognized until the presence of pesticide contaminants in food supplies caused alarm. The capability of plants to bioconcentrate environmental agents and activate promutagens into toxic metabolites is significant when one realizes the immense diversity of xenobiotics to which plants are intentionally and unintentionally exposed. Finally, we all must be attentive to the effects that toxic agents may have on the biosphere and the grave global consequences that would result in a disruption in the carbon cycle. DTIC

STUDIES IN NONLINEAR PROBLEMS OF ENERGY

B. J. Matkowsky Sep. 1994 17 p

(Contract DE-FG02-87ER-25027)
(DE95-001387; DOE/ER-25027/8) Avail: CASI HC A03/MF A01

The authors concentrate on modeling, analysis and large scale scientific computation of combustion and flame propagation phenomena, with emphasis on the transition from laminar to turbulent combustion. In the transition process a flame passed through a stage exhibiting increasingly complex spatial and temporal patterns which serve as signatures identifying each stage. Often the transitions arise via bifurcation. The authors investigate nonlinear dynamics, bifurcation and pattern formation in the successive stage of transition. They describe the stability of combustion waves, and transitions to combustion waves exhibiting progressively higher degrees of spatio-temporal complexity. One aspect of this research program is the systematic derivation of appropriate, approximate models from the original models governing combustion. The approximate models are then analyzed. The authors are particularly interested in understanding the basic mechanisms affecting combustion, which is a prerequisite to effective control of the process. They are interested in determining the effects of varying various control parameters, such as Nusselt number, Lewis number, heat release, activation energy, Damkohler number, Reynolds number, Prandtl number, Peclet number, etc. The authors have also considered a number of problems in self-propagating high-temperature synthesis (SHS), in which combustion waves are employed to synthesize advanced materials. Efforts are directed toward understanding fundamental mechanisms. DOE

FLUID DYNAMICS OF THE FREEBOARD IN A FLUIDIZED BED REACTOR Ph.D. Thesis
Willem Cornelis Verloop 31 May 1994 204 p
(PB95-134029; ISBN-90-370-0107-6) Avail: CASI HC A10/MF A03

The present study focuses on the fluid dynamics of the gas-particle freeboard flow, whereas a subsequent study will cover the chemistry. The objective of the present thesis is to increase the insight in the physical processes that govern the freeboard particle flow. Special attention has to be paid to the lateral transport of particles and the often observed phenomenon of a downflowing wall layer of solids, which has not been explained satisfactorily up to now. In order to achieve this, detailed experiments have to be performed which provide data on the local flow structure. In addition, the freeboard flow has to be modeled at least two-dimensionally, incorporating the essential physical processes. The resulting model of the freeboard flow should firstly be capable of predicting the local properties of both the gas flow and the particle flow. This prediction has to serve as a basis for the subsequent modeling of the freeboard chemistry. Secondly, the model should serve as a basis for studying the consequences of the scaling up a fluidized bed installation from lab scale to industrial size. NTIS

NONLINEAR INTERACTION BETWEEN A PAIR OF OBLIQUE MODES IN A SUPERSONIC MIXING LAYER: LONG-WAVE LIMIT Final Technical Report
Thomas F. Balsa and James Gartside Feb. 1995 61 p
(Grant NAG3-781)
(NASA-CR-197380; NAS 1.26:197380) Avail: CASI HC A04/MF A01

The nonlinear interaction between a pair of symmetric, oblique, and spatial instability modes is studied in the long-wave limit using asymptotic methods. The base flow is taken to be a supersonic mixing layer whose Mach number is such that the corresponding vortex sheet is marginally stable according to Miles' criterion. It is shown that the amplitude of the mode obeys a nonlinear integro-differential equation. Numerical solutions of this equation show that, when the obliqueness angle is less than pi/4, the effect of the nonlinearity is to enhance the growth rate of the instability. The solution terminates in a singularity at a finite streamwise location. This result is reminiscent of that obtained in the vicinity of the neutral point by other authors in several different types of flows. On the other hand, when the obliqueness angle is more than pi/4, the streamwise development of the amplitude is characterized by a series of modulations. This arises from the fact that the nonlinear term in the amplitude equation may be either stabilizing or destabilizing, depending on the value of the streamwise coordinate. However, even in this case the amplitude of the disturbance increases, though not as rapidly as in the case for which the angle is less than pi/4. Quite generally then, the nonlinear interaction between two oblique modes in a supersonic mixing layer enhances the growth of the disturbance. Author

GOVERNING EQUATIONS FOR MULTIPHASE HEAT AND MASS TRANSFER IN HYGROSCOPIC POROUS MEDIA WITH APPLICATIONS TO CLOTHING MATERIALS Final Report, Jan. - Jun. 1994
Phillip Gibson Nov. 1994 68 p
(AD-A286418; NATICK-TR-95/004) Avail: CASI HC A04/MF A01

Whitaker's theory of coupled heat and mass transfer through porous media was modified to include hygroscopic porous materials which can absorb liquid into the solid matrix. The system of equations described in this report should make it possible to evaluate the time-dependent transport properties of hygroscopic and non-hygroscopic clothing materials by including many important factors which are usually ignored in the analysis of heat and mass transfer through textile materials. The set of equations allows for the unsteady capillary wicking of sweat through fabric structure, condensation and evaporation of sweat within various layers of the clothing system, forced gas phase convection through the porous structure of a textile layer, and the swelling and shrinkage of fibers and yarns as they absorb/desorb liquid water and water vapor. DERIVATION OF A WAVENUMBER FILTER DESIGN FOR THE MEASUREMENT OF TURBULENT WALL PRESSURE FLUCTUATIONS Final Report
William L. Keith and Bruce M. Abraham 14 Nov. 1994 32 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A286421; NUWC-NPT-TR-10693) Avail: CASI HC A03

Measurement of the wavenumber-frequency spectrum o(kl,w) of turbulent wall pressure fluctuations requires a line array (wavenumber filter) of closely spaced sensors. However, the wide range of wavenumbers of the wall pressure fluctuations that contribute to the spectrum imposes constraints on sensor size, spacing, and number. In this study, the Corcos model of the wall pressure field is used in conjunction with recent experimental measurements to determine design parameters expressed in terms of boundary layer length and time scales. For the case of turbulent boundary layers at moderate to high Reynolds numbers, the resulting wavenumber design requires microfabrication technology. DTIC

SHOCK WAVE INTERACTIONS IN HYPERVELOCITY FLOW
S. R. Sanderson and B. Sturtevant Aug. 1994 10 p
(Contract F49620-93-1-0338)
(AD-A286507; AFOSR-94-0727TR) Avail: CASI HC A02/MF A01

The impingement of shock waves on blunt bodies in steady supersonic flow is known to cause extremely high local heat transfer rates and surface pressures. Although these problems have been studied in cold hypersonic flow, the effects of dissociative relaxation processes are unknown. In this paper we report a model aimed at determining the boundaries of the possible interaction regimes for an ideal dissociating gas. Local analysis about shock wave intersection points in the pressure-flow deflection angle plane with continuation of singular solutions is the fundamental tool employed. Further, we discuss an experimental investigation of the nominally two-dimensional mean flow that results from the impingement of an oblique shock wave on the leading edge of a cylinder. The effects of variations in shock impingement geometry were visualized using differential interferometry. Generally, real gas effects are seen to increase the range of shock impingement points for which enhanced heating occurs. They also reduce the type 4 interaction supersonic jet width and influence the type 2-3 transition process. DTIC

MEASUREMENT OF THE THERMAL PROPERTIES OF ELECTRICALLY CONDUCTING FLUIDS USING COATED TRANSIENT HOT WIRES
R. A. Perkins 1994 9 p Presented at the 12th Symposium on Energy Engineering Sciences, Argonne, IL, 27-29 Apr. 1994
(Contract DE-AI05-89ER-13992)
(DE94-017816; CONF-9404137-6) Avail: CASI HC A02/MF A01

Measurements of fluid thermal properties using the transient hot-wire technique are described. When bare hot wires are used in electrically conducting fluids there are additional measurement uncertainties due to the formation of electric double layers on the surfaces of the wires and the cell wall. If the electrical conductivity of the fluid is large enough there is also significant power generation in the fluid. These measurement uncertainties can be eliminated by electrically insulating the hot wires with a thin film. The use of tantalum hot wires with an anodized layer of tantalum pentoxide is demonstrated with measurements on nonpolar argon and polar 1,1,1,2 tetrafluorethane (R134a). Although coated tantalum hot wires have been used previously in a transient mode to measure the thermal conductivity of liquids, this work is the first demonstration of the use of coated wires to measure thermal conductivity in the liquid, vapor, and supercritical gas phases. We discuss two physical systems from separate disciplines that make use of the same algorithmic and mathematical structures to reduce the number of operations necessary to complete a realistic simulation. In the gravitational N-body problem, the acceleration of an object is given by the familiar Newtonian laws of motion and gravitation. The computational load is reduced by treating groups of bodies as single multipole sources rather than individual bodies. In the simulation of incompressible flows, the flow may be modeled by the dynamics of a set of N interacting vortices. Vortices are vector objects in three dimensions, but their interactions are mathematically similar to that of gravitating masses. The multipole approximation can be used to greatly reduce the time needed to compute the interactions between vortices. Both types of simulations were carried out on the Intel Touchstone Delta, a parallel MIMD computer with 512 processors. Timings are reported for systems of up to 10 million bodies, and demonstrate that the implementation scales well on massively parallel systems. The majority of the code is common between the two applications, which differ only in certain physics modules. In particular, the code for parallel tree construction and traversal is shared. DTIC

An analytic theory for the large (passive) scalar derivative skewness for turbulent transport in a mean scalar gradient has been devised using Lie Algebraic methods to solve the Hopf equation. This Reynolds independent skewness strongly contradicts Kolmogorov's theory occurs in shear flows, which are being studied numerically, emphasizing the analogies between scalar and momentum transport. CONDITIONAL STATISTICS IN A TURBULENT PREMIXED FLAME DERIVED FROM DIRECT NUMERICAL SIMULATION **c25**
Thierry Mantel and Robert W. Bilger (Sydney Univ., Australia.) *In its* Annual Research Briefs, 1994 Dec. 1994 p 3-27 (For primary document see N95-22437 06-34)
Avail: CASI HC A03/MF A04

The objective of this paper is to briefly introduce conditional moment closure (CMC) methods for premixed systems and to derive the transport equation for the conditional species mass fraction conditioned on the progress variable based on the enthalpy. Our statistical analysis will be based on the 3-D DNS database of Trouve and Poinsot available at the Center for Turbulence Research. The initial conditions and characteristics (turbulence, thermo-diffusive properties) as well as the numerical method utilized in the DNS of Trouve and Poinsot are presented, and some details concerning our statistical analysis are also given. From the analysis of DNS results, the effects of the position in the flame brush, of the Damkoehler and Lewis numbers on the conditional mean scalar dissipation, and conditional mean velocity are presented and discussed. Information concerning unconditional turbulent fluxes are also presented. The anomaly found in previous studies of counter-gradient diffusion for the turbulent flux of the progress variable is investigated. Derived from text

LEWIS NUMBER AND DAMKOHLER NUMBER EFFECTS IN VORTEX-FLAME INTERACTIONS **c25**
Jean-Michael Samaniego *In its* Annual Research Briefs, 1994 Dec. 1994 p 29-43 (For primary document see N95-22437 06-34)
Avail: CASI HC A03/MF A04

A combined experimental-numerical study of the interaction of a two-dimensional vortex pair with a plane premixed laminar flame has been carried out. The selected geometry is two-dimensional in order to allow for the use of quantitative line-of-sight measurement techniques and for comparisons with two-dimensional direct numerical simulations. The experiment is used to identify possible effects of the Lewis number and of radiative heat losses, and direct numerical simulations reproducing the experimental conditions are used to investigate the role of the Lewis number, of heat losses, and of multi-step kinetics. The heat losses considered in this study are essentially radiative losses from the burnt gases and do not include conductive losses to the walls. This report presents the final results of this study of vortex-flame interactions. The main result is the creation of experimental data sets of vortex-flame interactions, which demonstrate the importance of the Lewis and Damkohler numbers to the flame and which allow for comparison with direct numerical simulations. In turn, the comparison between experimental and numerical results shows that the Lewis number effects and complex chemistry play significant roles, which

can be reproduced using a two-step reaction mechanism.

FUNDAMENTAL MECHANISMS IN PREMIXED FLAME PROPAGATION VIA VORTEX-FLAME INTERACTIONS: NUMERICAL SIMULATIONS c25
Thierry Mantel *In its* Annual Research Briefs, 1994 Dec. 1994 p 45-75 (For primary document see N95-22437 06-34)
Avail: CASI HC A03/MF A04

The goal of the present study is to assess numerically the ability of single-step and two-step chemical models to describe the main features encountered during the interaction between a two-dimensional vortex pair and a premixed laminar flame. In the two-step mechanism, the reaction kinetics are represented by a first chain branching reaction A + X yields 2X and a second chain termination reaction X + X yields P. This paper presents the fundamental mechanisms occurring during vortex-flame interactions and the relative impact of the major parameters encountered in turbulent premixed flames and suspected of playing a role in quenching mechanism: (1) Influence of stretch is investigated by analyzing the contribution of curvature and tangential strain on the local structure of the flame. The effect of Lewis number on the flame response to a strained field is analyzed. (2) Radiative heat losses which are suspected to be partially or totally responsible for quenching are also investigated. (3) The effect of the diffusion of the radicals is studied using a two-step mechanism in which an intermediate species is present. The parameters of the two-step mechanism are entirely determined from physical arguments. (4) Precise quantitative comparisons between the DNS and the experimental results of Samaniego et al are performed. These comparisons concern the evolution of the minimum heat release rate found along the flame front during the interaction and the distribution of the heat release rate along the flame front. TRIPLE FLAMES AND FLAME STABILIZATION c25
James E. Broadwell *In its* Annual Research Briefs, 1994 Dec. 1994 p 77-78 (For primary document see N95-22437 06-34)
Avail: CASI HC A01/MF A04

It is now well established that when turbulent jet flames are lifted, combustion begins, i.e., the flame is stabilized, at an axial station where the fuel and air are partially premixed. One might expect, therefore, that the beginning of the combustion zone would be a triple flame. Such flames have been described; however, other experiments provide data that are difficult to reconcile with the presence of triple flames. In particular, laser images of CH and OH, marking combustion zones, do not exhibit shapes typical of triple flames, and, more significantly, the lifted flame appears to have a propagation speed that is an order of magnitude higher than the laminar flame speed. The speed of triple flames studied thus far exceeds the laminar value by a factor less than two. The objective of the present task is the resolution of the apparent conflict between the experiments and the triple flame characteristics, and the clarification of the mechanisms controlling flame stability. Being investigated are the resolution achieved in the experiments, the flow field in the neighborhood of the stabilization point, propagation speeds of triple flames, laboratory flame unsteadiness, and the importance of flame ignition limits in the calculation of triple flames that resemble lifted flames. FLAME PROPAGATION UNDER PARTIALLY-PREMIXED CONDITIONS c25
Gregory R. Ruetsch *In its* Annual Research Briefs, 1994 Dec. 1994 p 79-96 (For primary document see N95-22437 06-34)
Avail: CASI HC A03/MF A04

This study concentrates on developing a better understanding of triple flames. We relax the assumption of zero heat release, address the issue of stabilization, and, in order to investigate the role that heat release plays in flame propagation in partially premixed combustion, we return to a simple flow field and investigate the behavior of flames in a laminar environment. We solve the compressible Navier-Stokes equations in a two-dimensional domain. At the boundaries, we use an inflow boundary condition on the left and nearly-perfect reflective boundary conditions, required to avoid pressure drift, at the outflow and sides. After the flow and flame are initialized, the mixture fraction is varied at the inlet from its uniform stoichiometric value to a tanh profile varying from zero to one. As the mixture fraction gradient reaches the flame surface only the centerline is exposed to the stoichionetric mixture fraction and locally maintains the planar flame speed and reaction rate. Above this point the mixture is fuel rich, and below fuel lean. As a result, these regions of non-unity equivalence ratio burn less, the reaction rate drops, and the local flame speed is reduced. The excess fuel and oxidizer then combine behind the premixed flame along the stoichiometric surface and burn in a trailing diffusion flame. Thus the 'triple' flame refers to the fuel-rich premixed flame, the fuel-lean premixed flame, and the trailing diffusion flame. Due to heat release, the normal velocity across the flame is increased, whereas the tangential component remains unchanged. Far-field flame speed, local flame speed, and their differences are shown as a function of the local mixing thickness. It was also determined that the lateral position of the flame affects stabilization, and the distribution of the reaction rate along the premixed wings of triple flames affects flame propagation. TURBULENCE MODELING FOR SEPARATED FLOW
Paul A. Durbin *In its* Annual Research Briefs, 1994 Dec. 1994 p 97-105 (For primary document see N95-22437 06-34)
Avail: CASI HC A02/MF A04

Two projects are described in this report. The first involves assessing turbulence models in separated flow. The second addresses the anomalous behavior of certain turbulence models in stagnation point flow. The primary motivation for developing turbulent transport models is to provide tools for computing non-equilibrium, or complex, turbulent flows. Simple flows can be analyzed using data correlations or algebraic eddy viscosities, but in more complicated flows such as a massively separated boundary layer, a more elaborate level of modeling is required. It is widely believed that at least a two-equation transport model is required in such cases. The transport equations determine the evolution of suitable velocity and time-scales of the turbulence. The present study included assessment of second-moment closures in several separated flows, including sharp edge separation; smooth wall, pressure driven separation; and unsteady vortex shedding. Flows with mean swirl are of interest for their role in enhancing mixing both by turbulent and mean motion. The swirl can have a stabilizing effect on the turbulence. An axi-symmetric extension to the INS-2D computer program was written adding the capability of computing swirling flow. High swirl can produce vortex breakdown on the centerline of the jet and it occurs in various combustors. Derived from text

NOTES ON ROTATING TURBULENCE
Otto Zeman *In its* Annual Research Briefs, 1994 Dec. 1994 p 107-114 (For primary document see N95-22437 06-34)
Avail: CASI HC A02/MF A04

This work investigates the turbulent constitutive relation when turbulence is subjected to solid body rotation. Laws regarding spectra and asymptotic decay of rotating homogeneous turbulence were confirmed through large-eddy simulation (LES) computations. Rotating turbulent flows exist in many industrial, geophysical, and astrophysical applications. From Lagrangian analysis a relation between turbulent stress and strain in rotating homogeneous turbulence was inferred. This relation was used to derive the spectral energy flux and, ultimately, the energy spectrum form. If the rotation wavenumber k(sub Omega) lies in the inertial subrange, then for wavenumbers less than k(sub Omega) the turbulence motions are affected by rotation and the energy spectrum slope is modified. Energy decay laws inferred in other reports and the present results suggest a modification of the epsilon model equation and eddy viscosity in k-epsilon models.

A DYNAMIC LOCALIZATION MODEL WITH STOCHASTIC BACKSCATTER
Daniele Carati and Sandip Ghosal *In its* Annual Research Briefs, 1994 Dec. 1994 p 115-125 (For primary document see N95-22437 06-34)
Avail: CASI HC A03/MF A04

The modeling of subgrid scales in large-eddy simulation (LES) has been rationalized by the introduction of the dynamic localization procedure. This method allows one to compute rather than prescribe the unknown coefficients in the subgrid-scale model. Formally, the LES equations are supposed to be obtained by applying to the Navier-Stokes equations a 'grid filter' operation. Though the subgrid stress itself is unknown, an identity between subgrid stresses generated by different filters has been derived. Although preliminary tests of the Dynamic Localization Model (DLM) with k-equation have been satisfactory, the use of a negative eddy viscosity to describe backscatter is probably a crude representation of the physics of reverse transfer of energy. Indeed, the model is fully deterministic. Knowing the filtered velocity field and the subgrid-scale energy, the subgrid stress is automatically determined. We know that the LES equations cannot be fully deterministic since the small scales are not resolved. This stems from an important distinction between equilibrium hydrodynamics and turbulence. In equilibrium hydrodynamics, the molecular motions are also not resolved. However, there is a clear separation of scale between these unresolved motions and the relevant hydrodynamic scales. The result of molecular motions can then be separated into an average effect (the molecular viscosity) and some fluctuations. Due to the large number of molecules present in a box with size of the order of the hydrodynamic scale, the ratio between fluctuations and the average effect should be very small (as a result of the 'law of large numbers'). For that reason, the hydrodynamic balance equations are usually purely deterministic. In turbulence, however, there is no clear separation of scale between small and large eddies. In that case, the fluctuations around a deterministic eddy viscosity term could be significant. An eddy noise would then appear through a stochastic term in the subgrid-scale model and could be the source of backscatter. Author

LARGE-EDDY SIMULATION OF A PLANE WAKE
Sandip Ghosal (Stanford Univ., CA.) and M. M. Rogers *In* Stanford Univ., Annual Research Briefs, 1994 Dec. 1994 p 127-141 (For primary document see N95-22437 06-34)
Avail: CASI HC A03/MF A04

Previously the theoretical development leading to the dynamic localization model (DLM) for large-eddy simulation (LES) was presented. The method has been successfully applied to isotropic turbulence, channel flow, and the flow over a backward-facing step. Here we apply the model to the computation of the temporally developing place wake. The two main objectives of this project are: (1) Use the model to perform an LES of a time developing plane wake and compare the results with direction numerical simulation (DNS) data to see if important statistical measures can be readily predicted, and to provide a relative evaluation of the several versions of the model in terms of predictive capability and cost; and (2) If the tests in (1) show that the model generates reliable predictions, then use the LES to study various aspects of the physics of turbulent wakes and mixing layers. LOCAL DYNAMIC SUBGRID-SCALE MODELS IN CHANNEL FLOW
William H. Cabot *In its* Annual Research Briefs, 1994 Dec. 1994 p 143-159 (For primary document see N95-22437 06-34)
Avail: CASI HC A03/MF A04

The dynamic subgrid-scale (SGS) model has given good results in the large-eddy simulation (LES) of homogeneous isotropic or shear flow, and in the LES of channel flow, using averaging in two or three homogeneous directions (the DA model). In order to simulate flows in general, complex geometries (with few or no homogeneous directions), the dynamic SGS model needs to be applied at a local level in a numerically stable way. Channel flow, which is inhomogeneous and wall-bounded flow in only one direction, provides a good initial test for local SGS models. Tests of the dynamic localization model were performed previously in channel flow using a pseudospectral code and good results were obtained. Numerical instability due to persistently negative eddy viscosity was avoided by either constraining the eddy viscosity to be positive or by limiting the time that eddy viscosities could remain negative by co-evolving the SGS kinetic energy (the DLk model). The DLk model, however, was too expensive to run in the pseudospectral code due to a large near-wall term in the auxiliary SGS kinetic energy (k) equation. One objective was then to implement the DLk model in a second-order central finite difference channel code, in which the auxiliary k equation could be integrated implicitly in time at great reduction in cost, and to assess its performance in comparison with the plane-averaged dynamic model or with no model at all, and with direct numerical simulation (DNS) and/or experimental data. Other local dynamic SGS models have been proposed recently, e.g., constrained dynamic models with random backscatter, and with eddy viscosity terms that are averaged in time over material path lines rather than in space. Another objective was to incorporate and test these models in channel flow. Author

UNSTRUCTURED-GRID LARGE-EDDY SIMULATION OF FLOW OVER AN AIRFOIL **c02**
Kenneth Jansen *In its* Annual Research Briefs, 1994 Dec. 1994 p 161-173 (For primary document see N95-22437 06-34)
Avail: CASI HC A03/MF A04

Historically, large-eddy simulations (LES) have been restricted to simple geometries where spectral or finite difference methods have dominated due to their efficient use of structured grids. Structured grids, however, not only difficulty representing complex domains and adapting to complicated flow features, but also are rather inefficient for simulating flows at high Reynolds numbers. The lack of efficiency stems from the need to resolve the viscous sublayer, which requires very fine resolution in all three directions near the wall. Structured grids make use of a stretching to reduce the normal grid spacing but must carry the fine resolution in the streamwise and spanwise directions throughout the domain. The unnecessarily fine grid for much of the domain leads to disturbingly high grid estimates. Chapman (1979), and later Moin & Jimenez (1993), pointed out that, in order to advance the technology to airfoils at flight Reynolds numbers, structured grids must be abandoned in lieu of what are known as nested or unstructured grids. The finite element method can efficiently solve the Navier-Stokes equations on unstructured grids. Although the CPU cost per time step per element is somewhat higher than structured grid methods, this effect is more than offset by the reduction in the number of elements. The use of unstructured grids, coupled with the advances in dynamic subgrid-scale modeling such as those made by Germano et al. (1991) and Ghosal et al. (1994), make LES of an airfoil tractable. We have chosen the NACA 4412 airfoil at maximum lift as the first simulation since this flow has not been successfully simulated with the Reynolds-averaged Navier-Stokes equations. Author

LARGE-EDDY SIMULATION OF FLOW THROUGH A PLANE, ASYMMETRIC DIFFUSER
Hans-Jakob Kaltenbach *In its* Annual Research Briefs, 1994 Dec. 1994 p 175-184 (For primary document see N95-22437 06-34)
Avail: CASI HC A02/MF A04

A challenge for traditional turbulence modeling, based on the Reynolds averaged Navier-Stokes equations, remains the accurate prediction of 'mild', adverse pressure-gradient driven separation from a smooth surface. With this study we want to explore the capability of large-eddy simulation to predict the separation which occurs on the deflected wall of an asymmetric, plane diffuser with opening angle of 10 deg. The flow through the plane diffuser exhibits some additional interesting physical phenomena which make it a challenging test case. In addition to 'mild' separation about halfway down the deflected ramp, the flow is characterized by a small backflow zone with stalled fluid in the rear part of the expanding section. The turbulent flow entering the diffuser is subject to combined adverse and radial pressure gradients stemming from the convex curvature. Finally the flow recovers into a developed, turbulent channel flow in the outlet section. Obi et al. provide measurements of mean flow, Reynolds stresses, and pressure recovery, which were obtained by means of LDV in a wind tunnel. The objective of this study is to investigate whether LES with the standard dynamic model is able to accurately predict the flow in the one-sided diffuser and to explore the resolution requirements and associated costs. LARGE-EDDY SIMULATION OF A BOUNDARY LAYER WITH CONCAVE STREAMWISE CURVATURE
Thomas S. Lund *In its* Annual Research Briefs, 1994 Dec. 1994 p 185-195 (For primary document see N95-22437 06-34)
Avail: CASI HC A03/MF A04

Turbulence modeling continues to be one of the most difficult problems in fluid mechanics. Existing prediction methods are well developed for certain classes of simple equilibrium flows, but are still not entirely satisfactory for a large category of complex non-equilibrium flows found in engineering practice. Direct and large-eddy simulation (LES) approaches have long been believed to have great potential for the accurate prediction of difficult turbulent flows, but the associated computational cost has been prohibitive for practical problems. This remains true for direct simulation but is no longer clear for large-eddy simulation. Advances in computer hardware, numerical methods, and subgrid-scale modeling have made it possible to conduct LES for flows or practical interest at Reynolds numbers in the range of laboratory experiments. The objective of this work is to apply ES and the dynamic subgrid-scale model to the flow of a boundary layer over a concave surface. Author

EXPERIMENTAL INVESTIGATIONS OF ON-DEMAND VORTEX GENERATORS
Seyed G. Saddoughi *In its* Annual Research Briefs, 1994 Dec. 1994
p 197-203 (For primary document see N95-22437 06-34)
Avail: CASI HC A02/MF A04

Conventional vortex generators as found on many civil aircrafts are mainly for off-design conditions - e.g. suppression of separation or loss of aileron power when the Mach number accidentally rises above the design (cruise) value. In normal conditions they perform no useful function and exert a significant drag penalty. Recently there have been advances in new designs for passive vortex generators and boundary layer control. While traditionally the generators heights were of the order of the boundary layer thickness (delta), recent advances have been made where generators of the order of delta/4 have been shown to be effective. The advancement of MIcro-Electro-Mechanical (MEM) devices has prompted several efforts in exploring the possibility of using such devices in turbulence control. These new devices offer the possibility of boundary layer manipulation through the production of vortices, momentum jets, or other features in the flow. However, the energy output of each device is low in general, but they can be used in large numbers. Therefore, the possibility of moving from passive vortex generators to active (on-demand) devices becomes of interest. Replacement of fixed rectangular or delta-wing generators by devices that could be activated when needed would produce substantial economies. Our proposed application is not strictly 'active' control: the vortex generators would simply be switched on, all together, when needed (e.g. when the aircraft Mach number exceeded a certain limit). To this extent our scheme is simpler; however, to promote mixing and suppress separation we desire to deposit longitudinal vortices into the outer layer of the boundary layer as in conventional vortex generators. This requires a larger device although an alternative might be an array of smaller devices, for example, a longitudinal row with phase differences in the modulation signals so that the periodic vortices join up. The vortex pair with common flow up has the advantage that it will naturally drift away from the surface, but the disadvantage is that the net vorticity is zero so that the pair is eventually obliterated by turbulent mixing, rather than simply being diffused as in the case of a single vortex. It should be possible to devise alternative shapes of cavity wall so that the jet emerges obliquely and produces net longitudinal vorticity. Author

DIRECT NUMERICAL SIMULATIONS OF ON-DEMAND VORTEX GENERATORS: MATHEMATICAL FORMULATION
Petros Koumoutsakos *In its* Annual Research Briefs, 1994 Dec. 1994
p 205-214 (For primary document see N95-22437 06-34)
Avail: CASI HC A02/MF A04

The objective of the present research is the development and application of efficient adaptive numerical algorithms for the study, via direct numerical simulations, of active vortex generators. We are using innovative computational schemes to investigate flows past complex configurations undergoing arbitrary motions. Some of the questions we try to answer are: Can and how may we control the dynamics of the wake? What is the importance of body shape and motion in the active control of the flow? What is the effect of three-dimensionality in laboratory experiments? We are interested not only in coupling our results to ongoing, related experimental work, but furthermore to develop an extensive database relating the above mechanisms to the vortical wake structures with the long-range objective of developing feedback control mechanisms. This technology is very important to aircraft, ship, automotive, and other industries that require predictive capability for fluid mechanical problems. The results would have an impact in high angle of attack aerodynamics and help design ways to improve the efficiency of ships and submarines (maneuverability, vortex induced vibration, and noise). DRAG REDUCTION STRATEGIES
D. Christopher Hill *In its* Annual Research Briefs, 1994 Dec. 1994
p 215-218 (For primary document see N95-22437 06-34)
Avail: CASI HC A01/MF A04

previously a description was given of an active control scheme using wall transpiration that leads to a 15% reduction in surface skin friction beneath a turbulent boundary layer, according to direct numerical simulation. In this research brief further details of that scheme and its variants are given together with some suggestions as to how sensor/actuator arrays could be configured to reduce surface drag. The research which is summarized here was performed during the first half of 1994. This research is motivated by the need to understand better how the dynamics of near-wall turbulent flow can be modified so that skin friction is reduced. The reduction of turbulent skin friction is highly desirable in many engineering applications. Experiments and direct numerical simulations have led to an increased understanding of the cycle of turbulence production and transport in the boundary layer and raised awareness of the possibility of disrupting the process with a subsequent reduction in turbulent skin friction. The implementation of active feedback control in a computational setting is a viable approach for the investigation of the modifications to the flow physics that can be achieved. Bewley et al. and Hill describe how ideas from optimal control theory are employed to give 'sub-optimal' drag reduction schemes. The objectives of the work reported here is to investigate in greater detail the assumptions implicit within such schemes and their limitations. It is also our objective to describe how an array of sensors and actuators could be arranged and interconnected to form a 'smart' surface which has low skin friction. Author

OPTIMAL ACTIVE CONTROL FOR BURGERS EQUATIONS
Yutaka Ikeda *In* Stanford Univ., Annual Research Briefs, 1994 Dec. 1994 p 219-224 (For primary document see N95-22437 06-34)
Avail: CASI HC A02/MF A04

A method for active fluid flow control based on control theory is discussed. Dynamic programming and fixed point successive approximations are used to accommodate the nonlinear control problem. The long-term goal of this project is to establish an effective method applicable to complex flows such as turbulence and jets. However, in this report, the method is applied to stochastic Burgers equation as an intermediate step towards this goal. Numerical results are compared with those obtained by gradient search methods. Boundary layer flow transition has long been suggested as a potential noise source in both marine (sonar-dome self noise) and aeronautical (aircraft cabin noise) applications, owing to the highly transient nature of process. The design of effective noise control strategies relies upon a clear understanding of the source mechanisms associated with the unsteady flow dynamics during transition. Due to formidable mathematical difficulties, theoretical predictions either are limited to early linear and weakly nonlinear stages of transition, or employ acoustic analogy theories based on approximate source field data, often in the form of empirical correlation. In the present work, an approach which combines direct numerical simulation of the source field with the Lighthill acoustic analogy is utilized. This approach takes advantage of the recent advancement in computational capabilities to obtain detailed information about the flow-induced acoustic sources. The transitional boundary layer flow is computed by solving the incompressible Navier-Stokes equations without model assumptions, thus allowing a direct evaluation of the pseudosound as well as source functions, including the Lighthill stress tensor and the wall shear stress. The latter are used for calculating the radiated pressure field based on the Curle-Powell solution of the Lighthill equation. This procedure allows a quantitative assessment of noise source mechanisms and the associated radiation characteristics during transition from primary instability up to the laminar breakdown stage. In particular, one is interested in comparing the roles played by the fluctuating volume Reynolds stress and the wall-shear-stresses, and in identifying specific flow processes and structures that are effective noise generators. SMALL-SCALE BEHAVIOR IN DISTORTED TURBULENT BOUNDARY LAYERS AT LOW REYNOLDS NUMBER
Seyed G. Saddoughi *In its* Annual Research Briefs, 1994 Dec. 1994 p 243-261 (For primary document see N95-22437 06-34)
Avail: CASI HC A03/MF A04

During the last three years we have conducted high- and low-Reynolds-number experiments, including hot-wire measurements of the velocity fluctuations, in the test-section-ceiling boundary layer of the 80- by 120-foot Full-Scale Aerodynamics Facility at NASA Ames Research Center, to test the local-isotropy predictions of Kolmogorov's universal equilibrium theory. This hypothesis, which states that at sufficiently high Reynolds numbers the small-scale structures of turbulent motions are independent of large-scale structures and mean deformations, has been used in theoretical studies of turbulence and computational methods such as large-eddy simulation; however, its range of validity in shear flows has been a subject of controversy. The present experiments were planned to enhance our understanding of the local-isotropy hypothesis. Our experiments were divided into two sets. First, measurements were taken at different Reynolds numbers in a plane boundary layer, which is a 'simple' shear flow. Second, experiments were designed to address this question: will our criteria for the existence of local isotropy hold for 'complex' nonequilibrium flows in which extra rates of mean strain are added to the basic mean shear? TRANSVERSE VORTICITY MEASUREMENTS IN THE NASA AMES 80 X 120 WIND TUNNEL BOUNDARY LAYER
John F. Foss, D. G. Bhol, F. D. Bramkamp (Technische Hochschule, Aachen, Germany.), and J. G. Klewicki (Utah Univ., Salt Lake City, UT.) *In* Stanford Univ. Annual Research Briefs, 1994 Dec. 1994 p 263-268 (For primary document see N95-22437 06-34)
Avail: CASI HC A02/MF A04

The MSU compact four-wire transverse vorticity probe permits omega(sub z)(t) measurements in a nominally 1 sq mm domain. Note that a conventional coordinate system is used with x and y in the streamwise and normal directions respectively. The purpose of this investigation was to acquire time series data in the same access port at the ceiling of the 80 ft x 120 ft wind tunnel (NASA Ames Research Center) as earlier used by the Wallace group from the University of Maryland and to compare the present results with those of the three-component vorticity probe used in that earlier study. EXPERIMENTAL AND NUMERICAL STUDY OF THE INTERMITTENCY EXPONENT MU
Alexander Praskovsky *In its* Annual Research Briefs, 1994 Dec. 1994 p 269-286 (For primary document see N95-22437 06-34)
Avail: CASI HC A03/MF A04

After publication of the Kolmogorov refined similarity hypotheses, the small-scale intermittency of the energy dissipation field became a central problem in fully developed turbulence (FDT). This phenomenon has been studied in many different ways, e.g. by searching for corrections to scaling exponents in the inertial range velocity structure functions. A direct measure of this intermittency is, however, available by studying the local rate of energy dissipation, and it may be quantitatively characterized by the intermittency exponent mu. As far as we know, nobody has posed an obvious question: Is the intermittency exponent mu a unique constant, i.e., are the values mu(sub kappa), mu(sub epsilon), mu(sub r), mu(sub b), and mu(sub e) the same at high Reynolds numbers, or do they create a set of different (and perhaps independent) exponents? This paper addresses the above question using the high Reynolds number experiments. Derived from text

ON THE DYNAMICS OF SMALL-SCALE VORTICITY IN ISOTROPIC TURBULENCE
Javier Jimenez (Stanford Univ., CA.) and A. A. Wray *In* Stanford Univ., Annual Research Briefs, 1994 Dec. 1994 p 287-312 (For primary document see N95-22437 06-34)
Avail: CASI HC A03/MF A04

It was previously shown that the strong vorticity in isotropic turbulence is organized into tubular vortices ('worms') whose properties were characterized through the use of full numerical simulations at several Reynolds numbers. At the time most of the observations were kinematic, and several scaling laws were discovered for which there was no theoretical explanation. In the meantime, further analysis of the same fields yielded new information on the generation of the vortices, and it was realized that even if they had to be formed by stretching, they were at any given moment actually compressed at many points of their axes. This apparent contradiction was partially explained by postulating axial inertial waves induced by the nonuniformity of the vortex cores, which helped to 'spread' the axial strain and allowed the vortices to remain compact even if not uniformly stretched. The existence of such solutions was recently proved numerically. The present report discusses a set of new numerical simulations of isotropic turbulence, and a reanalysis of the old ones, in an effort to prove or disprove the presence of these waves in actual turbulent flows and to understand the dynamics, as opposed to the kinematics, of the vortices. FORCED FREE-SHEAR LAYER MEASUREMENTS
Richard L. LeBoeuf *In its* Annual Research Briefs, 1994 Dec. 1994 p 313-338 (For primary document see N95-22437 06-34)
Avail: CASI HC A03/MF A04

Detailed three-dimensional three-component phase averaged measurements of the spanwise and streamwise vorticity formation and evolution in acoustically forced plane free-shear flows have been obtained. For the first time, phase-averaged measurements of all three velocity components have been obtained in both a mixing layer and a wake on three-dimensional grids, yielding the spanwise and streamwise vorticity distributions without invoking Taylor's hypothesis. Initially, two-frequency forcing was used to phase-lock the roll-up and first pairing of the spanwise vortical structures in a plane mixing layer. The objective of this study was to measure the near-field vortical structure morphology in a mixing layer with 'natural' laminar initial boundary layers. For the second experiment the second and third subharmonics of the fundamental roll-up frequency were added to the previous two-frequency forcing in order to phase-lock the roll-up and first three pairings of the spanwise rollers in the mixing layer. The objective of this study was to determine the details of spanwise scale changes observed in previous time-averaged measurements and flow visualization of unforced mixing layers. For the final experiment, single-frequency forcing was used to phase-lock the Karman vortex street in a plane wake developing from nominally two-dimensional laminar initial boundary layers. The objective of this study was to compare measurements of the three-dimensional structure in a wake developing from 'natural' initial boundary layers to existing models of wake vortical structure. NUMERICAL STUDY OF BOUNDARY LAYER INTERACTION WITH SHOCKS: METHOD AND CODE VALIDATION
Nikolaus A. Adams *In its* Annual Research Briefs, 1994 Dec. 1994 p 339-356 (For primary document see N95-22437 06-34)
Avail: CASI HC A03/MF A04

A major problem in modeling of turbulent supersonic flows is the correct assessment of viscous-inviscid interaction problems. Of particular interest is the interaction of boundary layers with shocks. Present turbulence models give in most cases unsatisfactory results in the region of rapid distortion and in the separation region (if one is present) in particular with regard to mean flow profiles and turbulence quantities. The objective of the present work is the direct numerical simulation of shock boundary layer interaction. This report summarizes the first phase during which a numerical method suitable for this problem has been developed and a computer code has been written and tested. Author

RESOLUTION REQUIREMENTS FOR VELOCITY GRADIENTS IN TURBULENCE
Javier Jimenez *In its* Annual Research Briefs, 1994 Dec. 1994 p 357-364 (For primary document see N95-22437 06-34)
Avail: CASI HC A02/MF A04

Since high resolution numerical simulations of turbulent flows, or experiments at high Reynolds numbers, represent a substantial investment in resources, the estimation of the minimum resolution required for the study of a given property has been the subject of continued interest. Different properties require, in general, different resolutions, and the present paper is dedicated to the requirements for the measurement of the probability distribution functions of the velocity gradients and, in particular, of their low order moments. The deviation of these quantities from the values corresponding to a Gaussian distribution was one of the first indications of the presence of Reynolds number-dependent intermittency and has been the object of recent interest as numerical simulations have become able to explore the distribution of gradients in the low Reynolds number range, while new experiments have extended the range to increasingly high Reynolds numbers. We will use progressive filtering of the results of numerical simulations of isotropic turbulence as a model for the effect of a sensor of finite size. The numerical issues will be addressed first to ensure that the simulations are fully resolved from the point of view of the velocity gradients. This will also give us an estimate for the numerical resolution required for the different quantities. Author

A METHOD FOR OBTAINING A STATISTICALLY STATIONARY TURBULENT FREE SHEAR FLOW
Stephen F. Timson, S. K. Lele, and R. D. Moser *In its* Annual Research Briefs, 1994 Dec. 1994 p 365-371 (For primary document see N95-22437 06-34)
Avail: CASI HC A02/MF A04

The long-term goal of the current research is the study of Large-Eddy Simulation (LES) as a tool for aeroacoustics. New algorithms and developments in computer hardware are making possible a new generation of tools for aeroacoustic predictions, which rely on the physics of the flow rather than empirical knowledge. LES, in conjunction with an acoustic analogy, holds the promise of predicting the statistics of noise radiated to the far-field of a turbulent flow. LES's predictive ability will be tested through extensive comparison of acoustic predictions based on a Direct Numerical Simulation (DNS) and LES of the same flow, as well as a priori testing of DNS results. The method presented here is aimed at allowing simulation of a turbulent flow field that is both simple and amenable to acoustic predictions. A free shear flow is homogeneous in both the streamwise and spanwise directions and which is statistically stationary will be simulated using equations based on the Navier-Stokes equations with a small number of added terms. Studying a free shear flow eliminates the need to consider flow-surface interactions as an acoustic source. The homogeneous directions and the flow's statistically stationary nature greatly simplify the application of an acoustic analogy. Author

DIRECT NUMERICAL SIMULATION OF INCOMPRESSIBLE AXISYMMETRIC FLOWS
Patrick Loulou *In its* Annual Research Briefs, 1994 Dec. 1994 p 373-378 (For primary document see N95-22437 06-34)
Avail: CASI HC A02/MF A04

In the present work, we propose to conduct direct numerical simulations (DNS) of incompressible turbulent axisymmetric jets and wakes. The objectives of the study are to understand the fundamental behavior of axisymmetric jets and wakes, which are perhaps the most technologically relevant free shear flows (e.g. combuster injectors, propulsion jet). Among the data to be generated are various statistical quantities of importance in turbulence modeling, like the mean velocity, turbulent stresses, and all the terms in the Reynolds-stress balance equations. In addition, we will be interested in the evolution of large-scale structures that are common in free shear flow. The axisymmetric jet or wake is also a good problem in which to try the newly developed b-spline numerical method. Using b-splines as interpolating functions in the non-periodic direction offers many advantages. B-splines have local support, which leads to sparse matrices that can be efficiently stored and solved. Also, they offer spectral-like accuracy that are C(exp O-1) continuous, where O is the order of the spline used; this means that derivatives of the velocity such as the vorticity are smoothly and accurately represented. For purposes of validation against existing results, the present code will also be able to simulate internal flows (ones that require a no-slip boundary condition). Implementation of no-slip boundary condition is trivial in the context of the b-splines. Author

DATABASES POST-PROCESSING IN TENSORAL
Eliot Dresselhaus *In its* Annual Research Briefs, 1994 Dec. 1994 p 379-390 (For primary document see N95-22437 06-34)
Avail: CASI HC A03/MF A04

The Center for Turbulent Research (CTR) post-processing effort aims to make turbulence simulations and data more readily and usefully available to the research and industrial communities. The Tensoral language, introduced in this document and currently existing in prototype form, is the foundation of this effort. Tensoral provides a convenient and powerful protocol to connect users who wish to analyze fluids databases with the authors who generate them. In this document we introduce Tensoral and its prototype implementation in the form of a user's guide. This guide focuses on use of Tensoral for post-processing turbulence databases. The corresponding document - the Tensoral 'author's guide' - which focuses on how authors can make databases available to users via the Tensoral system - is currently unwritten. Section 1 of this user's guide defines Tensoral's basic notions: we explain the class of problems at hand and how Tensoral abstracts them. Section 2 defines Tensoral syntax for mathematical expressions. Section 3 shows how these expressions make up Tensoral statements. Section 4 shows how Tensoral statements and expressions are embedded into other computer languages (such as C or Vectoral) to make Tensoral programs. We conclude with a complete example program. We have performed a number of experiments and have developed a theoretical analysis of the current scaling issues of a negatively biased probe in a plasma wake. The end product of the laboratory research performed in the large vacuum chamber JUMBO at Phillips Laboratory can be found in the associated publication. Theoretical assumptions have been analyzed qualitatively and quantitatively by the use of the POLAR computer code. For a plasma with a constant beam energy, the analysis shows that the I-V collection characteristics are unaffected by Mach variations for Mach numbers above the value of two. For the same case, the current was found to scale with the 3/7 power of the density. DTIC

AN EVALUATION OF 915-MHz RADAR WIND PROFILER/RASS BY TOWER AND SODAR MEASUREMENTS
S. Zhong, W. J. Shaw, and J. M. Hubbe Aug. 1994 4 p Presented at the 3rd International Symposium on Tropospheric Profiling: Needs and Technologies, Hamburg, Germany, 30 Aug. - 2 Sep. 1994
(Contract DE-AC06-76RL-01830)
(DE94-018913; PNL-SA-24487; CONF-9408118-3) Avail: CASI HC A01/MF A01

The accuracy and precision of the 915-MHz low-atmosphere wind profiler/RASS have been investigated through comparisons with other better-understood instruments such as rawinsonde (Strauch et al., 1987 and May et al., 1989), sodar (Neff and Wilczak, 1993), and tower instruments (Ye et al., 1993). These studies have provided useful information as well as confidence in the performance of this new technology in boundary-layer research and monitoring. However, because the accuracy of the profiler/RASS measurements depends to a large degree on the strength and homogeneity of small-scale turbulence and the amount of moisture in the atmosphere, the performance of the profiler may change significantly from one environment to another. As the radar wind profiler/RASS technology becomes more widely applied to a variety of research applications and moves toward operational wind, temperature, and eventually flux profiling, it is crucial to quantify its performance under different environmental and meteorological conditions. South-central Washington is a semi-arid shrub-steppe environment with an average annual precipitation of only about 15 cm, which is significantly different from the other locations where comparative studies have been conducted. The performance of the RADIAN 915-MHz wind profiler/RASS in such an environment was evaluated using data from standard instruments mounted on a 120-m meteorological tower and a nearby sodar at the Hanford Meteorological Station. The results of this evaluation are presented in this paper. DOE

HYDROSTATIC FORCE SENSOR
M. S. Evans, R. S. Stoughton, and H. Kazerooni (California Univ., Berkeley, CA.) Aug. 1994 5 p Presented at the 5th International Symposium on Robotics and Manufacturing, Maui, HI, 14-18 Aug. 1994
(Contract DE-AC06-76RL-01830)
(DE94-018923; PNL-SA-24676; CONF-940859-26) Avail: CASI HC A01/MF A01

This paper presents a theoretical and experimental investigation of a new kind of force sensor which detects forces by measuring an induced pressure change in a material of large Poisson's ratio. In this investigation we develop mathematical expressions for the sensor's sensitivity and bandwidth, and show that its sensitivity can be much larger and its bandwidth is usually smaller than those of existing strain-gage-type sensors. This force sensor is well-suited for measuring large but slowly varying forces. It can be installed in a space smaller than that required by existing sensors. DOE

DEVELOPMENT OF SOLID STATE MOISTURE SENSORS FOR SEMICONDUCTOR FABRICATION APPLICATIONS
K. B. Pfeifer, M. J. Kelly, T. R. Guilinger, D. W. Peterson, J. N. Sweet, and M. R. Tuck 1994 12 p Presented at the SEMATECH: Symposium on Contamination Free Manufacturing, San Jose, CA, 4-6 Oct. 1994
(Contract DE-AC04-94AL-85000)
(DE94-015771; SAND-94-1533C; CONF-9410161-1) Avail: CASI HC A03/MF A01

We describe the design and fabrication of two types of solid state moisture sensors, and discuss the results of an evaluation of the sensors for the detection of trace levels of moisture in semiconductor process gases. The first sensor is based on surface acoustic wave (SAW) technology. A moisture sensitive layer is deposited onto a SAW device, and the amount of moisture adsorbed on the layer produces a proportional shift in the operating frequency of the device. Sensors based on this concept have excellent detection limits for moisture in inert gas (100 ppb) and corrosive gas (150 ppb in HCl). The second sensor is a simple capacitor structure that uses porous silicon as a moisture-sensitive dielectric material. The detection limits of these sensors for moisture in inert gas are about 700 ppb prior to HCl exposure, and about 7 ppm following HCl exposure. DOE

MECHANISM OF THE AMPEROMETRIC RESPONSE OF A PROPOSED GLUCOSE SENSOR BASED ON A POLYPYRROLE-TUBULE-IMPREGNATED MEMBRANE Interim Report
Susumu Kuwabata and Charles R. Martin May 1994 29 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-82-K-0612)
(AD-A279836; TR-94) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Nolte et al recently proposed a new type of amperometric glucose sensor. This sensor is based on a microporous membrane that contains polypyrrole tubules within the pores of the membrane. The procedure for preparing these polypyrrole tubules was developed in this laboratory. Nolte et al claim that glucose oxidase can be irreversible adsorbed to the inside walls of these polypyrrole tubules and that the resulting device functions as a glucose sensor. Indeed, they claim that this device functions via direct electron transfer from the reduced enzyme to the polypyrrole tubule. We have recently explored the response characteristics of this proposed new sensor. Our results suggest that this sensor does not function in the manner proposed by Nolte et al. Instead, our results indicate that the device operates by direct electrochemical oxidation of glucose at the metal (Pt) film that is coated onto one face of the membrane. This is proven by the fact that the sensitivity of the device is improved when polypyrrole and glucose oxidase are not present in the membrane. DTIC

PRELIMINARY CONTROL SYSTEM DESIGN AND ANALYSIS FOR THE SPACE STATION FURNACE FACILITY THERMAL CONTROL SYSTEM
M. E. Jackson Washington Jan. 1995 39 p
(NASA-TM-108476; NAS 1.15:108476) Avail: CASI HC A03/MF A01

This report presents the Space Station Furnace Facility (SSFF) thermal control system (TCS) preliminary control system design and analysis. The SSFF provides the necessary core systems to operate various materials processing furnaces. The TCS is defined as one of the core systems, and its function is to collect excess heat from furnaces and to provide precise cold temperature control of components and of certain furnace zones. Physical interconnection of parallel thermal control subsystems through a common pump implies the description of the TCS by coupled nonlinear differential equations in pressure and flow. This report formulates the system equations and develops the controllers that cause the interconnected subsystems to satisfy flow rate tracking requirements. Extensive digital simulation results are presented to show the flow rate tracking performance. Author

AN AT-SEA EVALUATION OF AN INFRARED/RESISTANCE TEMPERATURE DEVICE FOR AIR/SEA-SURFACE TEMPERATURE MEASUREMENTS Final Technical Report, Oct. 1992 - Sep. 1993
W. L. Patterson Mar. 1994 25 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A279672; NCCOSC/RDT/E-TR-1639) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Air and sea-surface temperatures were measured and recorded by the USS Kitty Hawk's meteorological personnel during a 6-month deployment period. Using infrared/resistance temperature devices (IR/RTD) and hand-held psychrometers, air and sea-surface temperature data were compiled. In comparing these data with data collected earlier by the USS Ranger, it became apparent that the shipboard use of the IR/RTD to measure sea-surface and air temperatures was not warranted. The IR/RTD suffered mechanical and electrical failures during both the USS Kitty Hawk and USSR Ranger measurement periods. Since repair and recalibration must be done at the manufacturer's facility, the device is inappropriate for shipboard use. In addition, the design of the battery-recharging unit does not conform to shipboard requirements for electrical grounding. Borne out by both the comments of the USS Kitty Hawk oceanographer and the large number of highly suspicious readings, additional training for observers is justified. Thus, training on the proper use and care of temperature-measuring devices could be made part of the Aerographer's Mate course curriculum and shipboard performance factors. DTIC

DYNAMIC RESPONSE OF PRESSURE MEASURING SYSTEMS
M. F. Lee Apr. 1993 23 p
(ARL-TR-32; AR-007-104) Copyright Avail: Issuing Activity (Aeronautical Research Labs., Melbourne, Australia)

The measurement of time varying pressures is limited when a pressure transmission line must be used. The type of pressure transducer can further limit the speed at which pressure changes can be observed. This report investigates these limitations by subjecting commonly used pressure line tubing and pressure transducers to a step pressure input. By spectrally analyzing the response to this step input a frequency response for the system can be determined. Author

RADIOACTIVE CHECK SOURCES FOR ALPHA AND BETA SENSITIVE RADIOLOGICAL INSTRUMENTATION

J. M. Barnett and J. E. Kane, II Jun. 1994 13 p Presented at the Health Physics Society Annual Meeting, San Francisco, CA, 27-30 Jun. 1994
(Contract DE-AC06-87RL-10930)
(DE94-016477; WHC-SA-2518; CONF-9406210-3) Avail: CASI HC A03/MF A01

Since 1991, the Westinghouse Hanford Company has examined the construction and use of alpha and beta radioactive check sources for calibrating instruments and for performing response checks of instruments used for operational and environmental radiation detection. The purpose of using a radioactive check source is to characterize the response of a radiation monitoring instrument in the presence of radioactivity. To accurately calibrate the instrument and check its response, the check source used must emulate as closely as possible the actual physical and isotopic conditions being monitored. The isotope employed and the physical methods used to fabricate the check source (among other factors) determine instrument response. Although information from applicable national and international standards, journal articles, books, and government documents was considered, empirical data collected is most valuable when considering the type of source to use for a particular application. This paper presents source construction methods, use considerations, and standard recommendations. The results of a Hanford Site evaluation of several types of alpha and beta sources are also given. EVALUATION OF Pd-Cr WIRES FOR STRAIN GAGE APPLICATION

Jih-Fen Lei (NYMA, Inc., Brook Park, OH.), L. C. Greer, III, and L. G. Oberle Feb. 1995 15 p
(Contract NAS3-27186; RTOP 505-62-50)
(NASA-TM-106857; E-9448; NAS 1.15:106857) Avail: CASI HC A03/MF A01

A newly developed alloy, palladium-13 weight percent chromium (Pd13Cr), was identified by United Technologies Research Center under a NASA contract to be the best material for high temperature strain gage applications. An electrical resistance strain gage that can provide accurate static strain measurement to a temperature higher than that of a commercially available gage is urgently needed in aerospace and aeronautics research. A strain gage made of a 25.4 micron (1 mil) diameter Pd13Cr wire has been recently demonstrated to be usable for static strain measurements to 800 C. This compares to the 400 C temperature limit of the commercially available strain gages. The performance of the Pd-Cr gage, however, strongly depends on the quality of the Pd13Cr wire. Four batches of Pd-Cr wires purchased from three different manufacturers were therefore evaluated to determine the best source of the wire for strain gage applications. The three suppliers were Precious Metal Institute in China, Sigmund Cohn Co., and G & S Titanium, Inc. in the United States. Two batches of wires obtained from Previous Metal Institute in 1987 and 1992, respectively are referred to herein as China87 and China92 wires. The mechanical, chemical and electrical properties of these wires, both as-received and after high temperature exposures at 800 C for 50 hours were analyzed. The elastic modulus and the failure strength of the wires were evaluated using a tensile test machine equipped with a laser speckle strain measurement system. The chemical and microstructural properties of the wires were inspected using a plasma atomic emission spectrometer and a scanning electron microscope (SEM) equipped with an energy dispersive X-ray spectroscope (EDS). The electrical stability and repeatability of the wires were determined by measuring the electrical resistance of the wires during three thermal cycles to 1000 C and a ten-hour soak at 1000 C. As a result of this study, the wire which has the highest strength, the least impurities content, the best oxidation resistance and the best electrical stability will be selected for upcoming strain gage applications. A THREE-DIMENSIONAL ORTHOGONAL LASER VELOCIMETER FOR THE NASA AMES 7- BY 10-FOOT WIND TUNNEL

Stephen E. Dunagan and Donald L. Cooper Feb. 1995 23 p Original contains color illustrations
(RTOP 505-59-54)
(NASA-TM-108864; A-95032; NAS 1.15:108864) Avail: CASI HC A03/MF A01; 1 functional color page

A three-component dual-beam laser-velocimeter system has been designed, fabricated, and implemented in the 7-by 10-Foot Wind Tunnel at NASA Ames Research Center. The instrument utilizes optical access from both sides and the top of the test section, and is configured for uncoupled orthogonal measurements of the three Cartesian coordinates of velocity. Bragg cell optics are used to provide fringe velocity bias. Modular system design provides great flexibility in the location of sending and receiving optics to adapt to specific experimental requirements. Near-focus Schmidt-Cassegrain optic modules may be positioned for collection of forward or backward scattered light over a large solid angle, and may be clustered to further increase collection solid angle. Multimode fiber optics transmit collected light to the photomultiplier tubes for processing. Counters are used to process the photomultiplier signals and transfer the processed data digitally via buffered interface controller to the host MS-DOS computer. Considerable data reduction and graphical display programming permit on-line control of data acquisition and evaluation of the incoming data. This paper describes this system in detail and presents sample data illustrating the system's capability. Author

DUAL ACTIVE SURFACE HEAT FLUX GAGE PROBE

Curt H. Liebert and Paul Kolodziej (National Aeronautics and Space Administration. Ames Research Center, Moffett Field, CA.) Feb. 1995 14 p Presented at the 41st International Instrumentation Symposium, Denver, CO, 7-11 May 1995; sponsored by Instrument Society of America
(RTOP 763-22-21)
(NASA-TM-106861; E-9466; NAS 1.15:106861) Avail: CASI HC A03/MF A01

A unique plug-type heat flux gage probe was tested in the NASA Ames Research Center 2x9 turbulent flow duct facility. The probe was fabricated by welding a miniature dual active surface heat flux gage body to the end of a hollow metal cylindrical bolt containing a metal inner tube. Cooling air flows through the inner tube, impinges onto the back of the gage body and then flows out through the annulus formed between the inner tube and the hollow bolt wall. Heat flux was generated in the duct facility with a Huels arc heater. The duct had a rectangular cross section and one wall was fabricated from 2.54 centimeter thick thermal insulation rigid surface material mounted onto an aluminum plate. To measure heat flux, the probe was inserted through the plate and insulating materials with the from of the gage located flush with the hot gas-side insulation surface. Absorbed heat fluxes measured with the probe were compared with absorbed heat fluxes measured with six water-cooled reference calorimeters. These calorimeters were located in a water-cooled metal duct wall which was located across from the probe position. Correspondence of transient and steady heat fluxes measured with the reference calorimeters and heat flux gage probe was generally within a satisfactory plus or minus 10 percent. This good correspondence was achieved even though the much cooler probe caused a large surface temperature disruption of 1000K between the metal gage and the insulation. However, this temperature disruption did not seriously effect the accuracy of the heat flux measurement. A current application for dual active surface heat flux gages is for transient and steady absorbed heat flux, surface temperature and heat transfer coefficient measurements on the surface of an oxidizer turbine inlet deflector operating in a space shuttle test bed engine. AN IN-LINE ULTRASONIC VISCOMETER

S. H. Sheen, H. T. Chien, and A. C. Raptis Oct. 1994 12 p Presented at the 21st Annual Review of Progress in Quantitative Nondestructive Evaluation Conference, Snowmass, CO, 31 Jul. - 5 Aug. 1994; sponsored by Iowa State Univ.
(Contract W-31-109-eng-38)
(DE95-002982; ANL/ET/CP-82855; CONF-9407123-2) Avail: CASI HC A03/MF A01

An in-line nonintrusive viscometer based on ultrasonic technology is described. The viscometer measures both acoustic and shear impedances of the fluid being monitored, from which both density and viscosity of the fluid are derived. The viscometer uses nominal-incidence wedges to transmit ultrasonic waves to the fluid. A simple model calculation is used to estimate the measurement accuracy and resolution. A laboratory prototype was built and tested. Results show that the viscometer can provide an accurate measurement of fluid density and viscosity over a wide viscosity range. Potential application of the viscometer to monitoring of non-Newtonian fluids is discussed. DOE

AN ECHELLE GRATING SPECTROMETER (EGS) FOR MID-IR REMOTE CHEMICAL DETECTION
C. G. Stevens, N. Thomas, P. Kuzmenko, and T. Alger Jul. 1994 11 p Presented at the Annual Meeting of the Society of Photo-Optical Instrumentation Engineers, San Diego, CA, 24-29 Jul. 1994
(Contract W-7405-eng-48)
(DE94-019310; UCRL-JC-118226; CONF-940723-28) Avail: CASI HC A03/MF A01

The availability of high performance two-dimensional InSb detectors enables the design and construction of mid-infrared spectrographs capable of obtaining high resolution spectra over extended spectral regions without moving components. Rugged, stable, cryo-cooled spectrographs suitable for remote field operation are now possible using prism-echelle cross dispersion designs. The authors discuss the design, fabrication, and performance of a high resolution mid-IR field spectrograph designed specifically for the detection of atmospheric-borne chemicals from airborne platforms. The instrument design provides maximum optical throughput covering the two atmospheric windows at 2.0-2.5 micron and 3.0-4.2 micron. DOE

(Contract DE-AC04-94AL-85000)
(DE94-019306; SAND-94-2293C; CONF-940857-1) Avail: CASI HC A01/MF A01

For future planetary science missions, the authors are developing a series of microinstruments using the techniques of silicon-based micromachining. Conventional instruments such as chemical sensors, charged particle analyzers and mass spectrometers are reduced in size and effective volume to the dimension of cubic centimeters, while maintaining or enhancing performance. Using wafer/wafer bonding techniques, selective chemical etching, thin Film growth, and high resolution lithography, complex three dimensional structures can be assembled. This paper discusses the design, implementation and performance of two new instruments: The Micromachined Bessel Box Auger Electron Spectrometer, and the Mars Soil Chemistry Experiment (MOx). DOE

SIGNAL TO NOISE IMPROVEMENTS WITH A NEW FAR-IR RAPID-SCAN MICHELSON INTERFEROMETER
C. J. Hirschmugl and G. P. Williams 1994 7 p Presented at the International Meeting on Synchrotron Radiation Instrumentation, Stony Brook, NY, 18-22 Jul. 1994 Submitted for publication
(Contract DE-AC02-76CH-00016)
(DE95-002416; BNL-60892; CONF-940714-36) Avail: CASI HC A02/MF A01

In this paper we discuss signal to noise issues in the infrared spectral region, presenting an update on instrumentation developments that have focused on this topic. We have been able to achieve reproducibilities in the 0.01 % range for spectra measured in around 1 minute on samples with an area of 1 sq mm illuminated with an fl 10 beam. We show how this result is consistent with the synchrotron source intensity and detector noise and we also show a comparison with a conventional globar source. For these new studies, a Nicolet(trademark) Impact 400 rapid scan Michelson Interferometer was modified by Pike Technologies and installed in vacuum at the U41R infrared beamline at the NSLS. The instrument is capable of scanning at an optical retardation rate of 3.2 cm/sec, and of a data collection frequency of 50 kHz triggered by the co-linear reference beam of a HeNe laser. A proprietary Nicolet(trademark) solid state beamsplitter was used to cover the range from 10-2500 cm(exp -1). Spectra were taken in reflection at grazing incidence off a single crystal Cu surface in ultra-high vacuum using liquid helium cooled detectors of the photoconductive type (Cu/Ge) or bolometric type (B/Si). The sample throughput for this system was 0.01 sq mm steradians. DOE

MULTIWIRE THERMOCOUPLES: FREQUENCY RESPONSE Final Report, Apr. 1992 - Dec. 1994
L. J. Forney (Georgia Inst. of Tech., Atlanta, GA.) and G. C. Fralick Dec. 1994 82 p
(Contract NCC3-302)
(NASA-TM-110510; NAS 1.15:110510; E19-X20-1) Avail: CASI HC A05/MF A01

Experimental measurements are made with a novel two wire thermocouple. Signals from two wires of unequal diameters are recorded from the thermocouple suspended in constant flow with a periodic temperature fluctuation. It is demonstrated that the reconstructed signal from the two wire thermocouple requires no compensation for omega less than or equal to 2 omega(sub 1) where omega is the natural frequency of the smaller wire. A compensation factor is recommended for larger frequencies omega greater than 2 omega(sub 1). Theory and experimental measurements are compared with a novel three wire thermocouple. Signals from three wires of unequal diameters are recorded from the thermocouple suspended in constant flow with a periodic temperature fluctuation. It is demonstrated that the reconstructed signal from the three wire thermocouple requires no compensation for omega less than or equal to 5 omega(sub 1) where omega (sub 1) is the natural frequency of the smaller wire. The latter result represents a significant improvement compared to previous work with two wire thermocouples. A correction factor has also been derived to account for wires of arbitrary diameter. Measurements are recorded for multiwire thermocouples consisting of either two or three wires of unequal diameters. Signals from the multiwire probe are recorded for a reversing gas flow with a periodic temperature fluctuation. It is demonstrated that the reconstructed signal from the multiwire thermocouple requires no compensation provided omega/omega(sub 1) is less than 2.3 for two wires or omega/omega(sub 1) is less than 3.6 for three wires where omega(sub 1) is the natural frequency of the smaller wire based on the maximum gas velocity. The latter results were possible provided Fourier transformed data were used and knowledge of the gas velocity is available. Author

TIME RESOLVED X-RAY DETECTION Final Report, 1 Jul. 1989 - 31 Dec. 1993
Peter M. Rentzepis 20 Apr. 1994 45 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract F49620-89-C-0104)
(AD-A279348; AFOSR-94-0303TR) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The goal of the project was to design, develop and construct an x-ray detector with high sensitivity and picosecond time resolution. This was achieved. A Ford Aerospace Charged Coupled Device, CCD, was utilized as the x-ray sensitive material around which the design and construction of the picosecond x-ray detector was built. This device has now become a commercial product sold, among other companies, by Photometrics Inc., and Princeton Research Inc. In addition we designed and built the first picosecond x-ray system. This system was utilized for the first ever picosecond x-ray diffraction experiments. The picosecond x-ray system was utilized in the oxidative fuel cell project to measure the decomposition of methanol and the change of the structure of its platinum catalyst. Another direct product of the work is the publication of 36 papers, in major scientific journals, and two patents. DTIC

SCALING OF SOLID STATE LASERS FOR SATELLITE POWER BEAMING APPLICATIONS
H. W. Friedman, G. F. Albrecht, and R. J. Beach Jan. 1994 11 p Presented at the OE/LASE 1994 Conference on Optics, Electro-Optics, and Laser Applications in Science and Engineering, Los Angeles, CA, 22-29 Jan. 1994
(Contract W-7405-eng-48)
(DE94-016366; UCRL-JC-114400; CONF-940142-43) Avail: CASI HC A03/MF A01

The power requirements for a satellite power beaming laser system depend upon the diameter of the beam director, the performance of the adaptive optics system, and the mission requirements. For an 8 meter beam director and overall Strehl ratio of 50%, a 30 kW laser at 850 nm can deliver an equivalent solar flux to a satellite at geostationary orbit. Advances in Diode Pumped Solid State Lasers (DPSSL) have brought these small, efficient and reliable devices to high average power and they should be considered for satellite power beaming applications. Two solid state systems are described: a diode pumped Alexandrite and diode pumped Thulium doped YAG. Both can deliver high average power at 850 nm in a single aperture. DOE

This study reports on the experimental development of a passively modelocked fiber laser. It is based on erbium doped fiber, similar to that used successfully in optical amplifiers. The focus of the work is to retain as much signal processing capability in the fiber medium as possible, and to select essential system components for ruggedness and straightforward field integration. The fiber ring laser here described uses the simplest and most compact configuration reported to date. The measured pulse durations are variable from 15 pico seconds to 1 nanosecond and are completely self starting. One self-modulation mechanism proposed and described is nonlinear polarization evolution. The surprising result is that this nonlinear effect is achieved in fiber at the low pump powers available from a compact diode source. This Kerr type effect generates modelocking in the fiber medium, and is somewhat analogous to the mechanism of operation in self-modelocked Ti:sapphire lasers. The construction of one of the fiber lasers is based on commercially available components most of which are integrated, allowing the final package size to be less than that of a notebook computer. Further work involves increased pulse stability control for applications in fiber communication systems and possibly fiber sensors. DTIC

(AD-A285105) Avail: CASI HC A03/MF A01

The solubilization of laser dyes in water with the aid of the polyelectrolyte, poly(methacrylic acid) (PMAA) has been studied. An important strategy was the isolation of dye species in the 'hypercoils' associated with the polyelectrolyte, as it is found a moderately acidic pH. Polymer-bound dyes in water display markedly enhanced emission yield, lifetime, and polarization. Dye materials are also less susceptible to photodegradation, since they are isolated in polymer domains away from adventitious quenchers. Also examined in the study was the possibility that two dyes could be co-bound within polymer domains and that energy transfer between the two would result in 'downshifting' of output emission wavelengths. Of the various amphiphilic media used for solubilizing organic dyes in water (e.g., detergent micelles, cyclodextrins), PMAA shows the greatest promise in term of fluorescence enhancement and compartmentalization or organized assembly of additives. These studies show promise for the protection of the dyes against undesirable photodegradation under flash excitation. DTIC

We have designed, constructed, and operated a 70-period microwiggler for free electrons lasers (FEL's). The device is a pulsed ferromagnetic-core electromagnet with a period of 8.8 mm, which generates an on-axis peak magnetic field of 4.2 kG. The pulses, of 0.5 msec duration, are generated at a rate of 0.5 Hz. Each field peak is independently tunable. We employed a novel tuning regimen to reduce the RMS spread in the peak amplitudes to 0.12%, the lowest value thus far attained in a sub-cm-period periodic magnetic field. DTIC

(DE94-017699; CONF-940586-1) Avail: CASI HC A03/MF A01

A combined theoretical and experimental effort to model various physical processes during laser ablation of solids (silicon) using a variety of computational techniques is described. Currently the focus of the modeling is on the following areas: (1) rapid transformations through the liquid and vapor phases under possibly nonequilibrium thermodynamic conditions induced by laser-solid interactions; (2) breakdown of the vapor into a plasma in the early stages of ablation through both electronic and photoionization processes; (3) hydrodynamic behavior of the vapor/plasma during and after ablation; and (4) effects of initial conditions in the vapor, in particular, the nature of the initial velocity distribution, on the characteristics of subsequent vapor expansion. Results from the modeling are compared with experimental observations where possible. DOE

ENHANCED OUTPUT OF SOFT X-RAY LASERS USING DOUBLE SLAB TARGETS
J. C. Moreno, J. Nilsen, and E. Chandler Jun. 1994 6 p Presented at the 4th International Colloquium on X-ray Lasers, Williamsburg, VA, 16-20 May 1994
(Contract W-7405-eng-48)
(DE94-016689; UCRL-JC-116927; CONF-940592-3) Avail: CASI HC A02/MF A01

Double slab neon-like niobium soft x-ray laser experiments have been performed using the Nova laser. The two slabs have their front surfaces facing in opposite directions with either a 300 (mu)m planar separation between them. Separate laser beams irradiate each slab with an intensity on target of 1.3 x 10(exp 14)W/sq cm. Best coupling was observed using a 300 (mu)m separation. The angular divergence of the laser is measured for single slab and double slab configurations. Comparisons to numerical models are discussed. DOE

MODELOCKING AND WAVEGUIDE AMPLIFIERS USING Cr:FORSTERITE AND Cr:YAG Final Report, Dec. 1992 - Dec. 1993
Clifford Pollack, Steven Johns, Michael Hayduk, Douglas Norton, and Mark Krol Aug. 1994 15 p
(Contract F30602-93-C-0003)
(AD-A285857; RL-TR-94-120) Avail: CASI HC A03/MF A01

Solid state laser systems have been demonstrated using Cr:YAG crystals. CW, regenerative modelocking, and self-modelocking have been achieved with pulses as short as 120 femtoseconds being transform limited. Thin film amplifiers based on Cr:forsterite on glass using a sol-gel deposition technique were fabricated and tested. Other techniques such as nanocrystal embedded in an index matching matrix made of polymers were explored. DTIC

SEMICONDUCTOR LASER JOINT STUDY PROGRAM WITH ROME LABORATORY Final Report, Feb. 1993 - Feb. 1994
William J. Schaff, Sean S. OKeefe, and Lester F. Eastman Sep. 1994 36 p
(Contract F30602-93-C-0083)
(AD-A285858; RL-TR-94-163) Avail: CASI HC A03/MF A01

A program to jointly study vertical-cavity surface emitting lasers (VCSEL) for high speed vertical optical interconnects (VOI) has been conducted under an ES&E between Rome Laboratory and Cornell University. Lasers were designed, grown, and fabricated at Cornell University. A VCSEL measurement laboratory has been designed, built, and utilized at Rome Laboratory. High quality VCSEL material was grown and characterized by fabricating conventional lateral cavity lasers that emitted at the design wavelength of 1.04 microns. The VCSEL's emit at 1.06 microns. Threshold currents of 16 mA at 4.8 volts were obtained for 30 microns diameter devices. Output powers of 5 mW were measured. This is 500 times higher power than from the light emitting diodes employed previously for vertical optical interconnects. A new form of compositional grading using a cosinusoidal function has been developed and is very successful for reducing diode series resistance for high speed interconnection applications. A flip-chip diamond package compatible with high speed operation of 16 VCSEL elements has been designed and characterized. A flip-chip device binding effort at Rome Laboratory was also designed and initiated. This report presents details of the one-year effort, including process recipes and results. DTIC

(AF Proj. 4600)
(AD-A285859; RL-TR-94-103) Avail: CASI HC A03/MF A01

This report presents two new smart pixels for use in optical computing and communications. These devices are configurable optical gates (COG's) that form the diode laser logic (DLL) family and spontaneous emission filtered laser amplifiers (SEFLA). DLL is a complete, new logic family comprised of Q-switched lasers and photodetectors. The lasers and detectors are monolithically integrated on multiple quantum well laser heterostructure with semi-insulating substrates. Preliminary results indicate an ON/OFF contrast ratio better than 500:1, gain in excess of 20, and variable 1/0 hysteresis characteristics. As a result, the devices can be cascaded to form more complex optical circuits. In addition to introducing the DLL family, a basic model is presented and the fabrication process is described in detail. The SEFLA combines an optical amplifier with a spontaneous emission filter in order to increase the signal-to-noise ratio by actively filtering out the spontaneous emission from the output signal. The filtering function is accomplished by integrating the amplifier with a semiconductor laser in such a way that the signal in the amplifier suppresses the gain in the laser. Unlike conventional optical amplifiers, these can, in principle, be cascaded without significantly decreasing the performance. DTIC

(Contract F49620-92-J-0504)
(AD-A285365; EOARD-TR-94-06) Avail: CASI HC A03/MF A01

This report describes preliminary attempts to investigate the feasibility of using liquid xenon as a solvent for novel laser systems. The objective was to see if the wide transparency range and low non radiative relaxation rates of this solvent can be exploited. A novel cell and filling system was successfully constructed. Barium fluoride windows repeatedly failed at a small fraction of their design pressure. They were successfully replaced with sapphire windows, but this severely limited the use of infrared diagnostics. As supplied xenon was found to be contaminated with excessive hydrocarbons (mainly methane) further limiting infrared diagnostics and nullifying the low non-radiative rate advantage of the solvent. Attempts to dissolve Rhodamine 6g and B were unsuccessful; there was limited evidence of p-terphenyl solubility. Overall the program was very seriously restricted by the combined problems of window failure and xenon contamination and the key concepts remain unproven, although methods to overcome these difficulties are identified. THREE-DIMENSIONAL LASER COOLING
Hiromi Okamoto, Andrew M. Sessler, and Dieter Moehl (European Organization for Nuclear Research, Geneva, Switzerland.) Jun. 1994 3 p Presented at the 4th European Particle Accelerator Conference, London, England, 27 Jun. - 1 Jul. 1994
(Contract DE-AC03-76SF-00098)
(DE94-017963; LBL-35899; CONF-940618-67) Avail: CASI HC A01/MF A01

To realize effective transverse laser cooling simultaneously with longitudinal laser cooling, two possibilities are theoretically studied. The schemes are both based on forced synchro-betatron coupling, which transfer the extremely effective longitudinal laser cooling action to transverse directions. The coupling is provided by an RF-cavity with a transverse variation of the longitudinal electric field (e.g. TM(sub 210) mode) or by a normal RF-cavity located at a position of finite dispersion. It is shown that, when a working point is close to the difference resonance, cooling in all three degrees of freedom is simultaneously obtained. DOE

(Contract DE-AC02-76CH-00016)
(DE94-017990; BNL-60737; CONF-9408146-6) Avail: CASI HC A01/MF A01

Inverse Cerenkov laser acceleration was demonstrated using an axicon optical system at the Brookhaven Accelerator Test Facility (ATF). The ATF S-band linac and a high power 10.6 MICROMETERSCO2 laser were used for the experiment. Experimental arrangement and the laser and the electron beams synchronization are discussed. The electrons were accelerated more than 0.7 MeV for a 34 MW CO2 laser power. More than 3.7 MeV acceleration was measured with 0.7 GW CO2 laser power, which is more than 20 times of the previous ICA experiment. The experimental results are compared with computer program TRANSPORT simulations. DOE

A URI PROGRAM FOR ULTRAVIOLET/EXTREME ULTRAVIOLET RESEARCH Final Report, 1 Feb. 1990 - 31 May 1993
John M. Madey 15 Apr. 1994 55 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Grant AF-AFOSR-0112-90)
(AD-A279159; AFOSR-94-0284TR) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The purpose of the 3-year effort was to facilitate research and training in free electron laser and synchrotron device physics in the UV/XUV portion of the spectrum and to undertake research in those areas of optical technology, materials science, chemistry and physics relevant to the requirements, and capabilities of these devices. As documented here, these objectives were accomplished by: (1) developing the basic instrumentation and operating support required to carry out the research and training objectives of the program; (2) providing direct support for research on selected topics to be carried out using these facilities; (3) encouraging graduate and undergraduate education in the scientific disciplines which form the basis of these technologies; and (4) promoting enhanced contacts with the scientific staff of the DOD laboratories. The successful completion of this effort has provided the FEL Laboratory, its faculty, students and collaborators with the unique resources required for the continuing pursuit of research in these fields. APPLICATION OF DIODE LASERS TO THE ISOTOPICALLY SELECTIVE DETERMINATION OF URANIUM IN OXIDES BY OPTOGALVANIC SPECTROSCOPY
J. P. Young, C. M. Barshick, R. W. Shaw, and J. M. Ramsey 1994 5 p Presented at the 7th International Symposium on Resonance Ionization Spectroscopy and Its Applications, Bernkastel-Kues, Germany, 3-8 Jul. 1994
(Contract DE-AC05-84OR-21400)
(DE94-018045; CONF-940706-1) Avail: CASI HC A01/MF A01

We have observed isotopically selective diode laser-excited optogalvanic effects in uranium at 778.42 and 776.19 nm. The samples were natural abundance uranium oxide, as well as depleted (0.3% U-235), natural (0.7% U-235) and enriched (9.75% U-235) uranium metal or powders. The measurements were carried out in a demountable-cathode glow discharge cell. Preliminary evaluations of precision for uranium isotopic ratios measured using this technique suggest that it should have broad analytical applications for uranium and other amenable actinides or lanthanides. COMPUTATIONAL MODEL OF DRILLING WITH HIGH RADIANCE PULSED LASERS
C. D. Boley Aug. 1994 12 p Presented at the Applications of Lasers and Electro-Optics, Orlando, FL, 17-20 Oct. 1994
(Contract W-7405-eng-48)
(DE94-018548; UCRL-JC-117078; CONF-9410189-1) Avail: CASI HC A03/MF A01

This paper describes a model of drilling by high radiance pulsed lasers. The model contains a one-dimensional description of heat transport below the bottom of the hole, hydrodynamic expansion of the vapor and compressed air, and light propagation through the vapor. The pressure and energy of the vapor are taken from a separate Saha equilibrium code. The boundary conditions at the vaporization surface include the formation of a Knudsen layer within which macroscopic fluid conditions are reached. The absorption mechanisms in the pertinent range of densities and temperatures are photoionization and inverse bremsstrahlung. The model has been applied to the case of drilling in stainless steel with green copper laser light, for peak input intensities ranging from 10(exp 8) to 5 x 10(exp 10) W/sq cm. Below 3 x 10(exp 8) W/sq cm , their is negligible absorption in the vapor and ablation increases rapidly with intensity. Above this point, ablation still generally increases with intensity, because of a combination of partially penetrating light and electron thermal conduction to the surface. The predicted ablation rates agree semiquantitatively with experiment. DOE

Beamlet is a full scale single beam prototype laser system, built to demonstrate the laser technology and performance of the 192 beam National Ignition Facility (NIF) fusion laser driver. Both laser systems apply multipass amplifier architectures. By passing the beam four times through the large aperture amplifier sections, the small signal gain during the first few passes is used efficiently to reduce expensive staged amplifier chains. The beamlet prototype laser integrates results of development programs for large aperture components: large aperture optical switch, polarizers, 2 x 2 multisegment amplifiers and new pulse generation and pre-amplification techniques. The authors report on performance test results of the recently completed 1 (omega)-laser section of Beamlet. DOE

DETECTION OPTIMIZATION USING LINEAR SYSTEMS ANALYSIS OF A CODED APERTURE LASER SENSOR SYSTEM
S. M. Gentry Sep. 1994 57 p
(Contract DE-AC04-94AL-85000)
(DE95-001112; SAND-94-0349) Avail: CASI HC A04/MF A01

Minimum detectable irradiance levels for a diffraction grating based laser sensor were calculated to be governed by clutter noise resulting from reflected earth albedo. Features on the earth surface caused pseudo-imaging effects on the sensor's detector arrays that resulted in the limiting noise in the detection domain. It was theorized that a custom aperture transmission function existed that would optimize the detection of laser sources against this clutter background. Amplitude and phase aperture functions were investigated. Compared to the diffraction grating technique, a classical Young's double-slit aperture technique was investigated as a possible optimized solution but was not shown to produce a system that had better clutter-noise limited minimum detectable irradiance. Even though the double-slit concept was not found to have a detection advantage over the slit-grating concept, one interesting concept grew out of the double-slit design that deserved mention in this report, namely the Barker-coded double-slit. This diffractive aperture design possessed properties that significantly improved the wavelength accuracy of the double-slit design. While a concept was not found to beat the slit-grating concept, the methodology used for the analysis and optimization is an example of the application of optoelectronic system-level linear analysis. The techniques outlined here can be used as a template for analysis of a wide range of optoelectronic systems where the entire system, both optical and electronic, contribute to the detection of complex spatial and temporal signals. REACTOR PUMPED LASER RESEARCH AT THE SANDIA NATIONAL LABORATORIES PULSED REACTOR FACILITIES
D. E. Bodette, D. R. Neal, D. A. McArthur, P. S. Pickard, G. Hebner, and R. Michie (Mission Research Corp., Albuquerque, NM.) 1994 9 p Presented at the Winter Meeting of the American Nuclear Society, Washington, DC, 13-18 Nov. 1994
(Contract DE-AC04-94AL-85000)
(DE95-002181; SAND-94-1978C; CONF-941102-31) Avail: CASI HC A02/MF A01

Sandia National Labs has been investigating concepts for high power lasers pumped directly by fission energy. The direct pumping of laser media with fission fragments offers the potential advantages of scaling to high powers and very long run times in a compact, self powered system. To investigate the potential of this concept, extensive experiments have been conducted in the Annular Core Research Reactor (ACRR) and the Sandia Pulsed Reactor (SPR-3). These experiments include laser physics tests, radiation effects tests on optical materials, and experiments to examine the scaling of reactor pumped lasers to high powers. The SPR-3 is a U-10%Mo fast burst reactor which is used for laser physics experiments. SPR-3 is capable of 70 to 1500 micro FWHM pulses generating up to several kW/cc excitation in a liter size laser cavity. The pulse widths greater than a few hundred microseconds are achieved using a pulse stretcher consisting of gram amounts of fissile material surrounded by moderator. The ACRR is a UO2BeO fueled epithermal reactor which is used for larger volume scaling and beam quality experiments. ACRR operates in both steady state and pulsed modes with pulse widths of 7 to 250 ms resulting in excitation rates of (approximately)2 to 100 W/cc in excitation volumes of up to 50 l. Experimental configurations on both reactors have included central cavity and external cavity locations. The experiments on SPR-3 have defined optimum conditions for efficient reactor pumping of rare gas lasers. This information has been used to define scaling experiments now in progress in the ACRR. CHEMICAL LASERS EMITTING IN THE VISIBLE SPECTRUM: METASTABLE OXYGEN REACTIONS AND YOSHIDA LASER Final Report [LASERS CHIMIQUES EMETTANT DANS LE VISIBLE: REACTIONS DE L'OXYGENE METASTABLE ET LASER YOSHIDA]

1994 35 p In FRENCH Sponsored by Direction des Recherches, Etudes et Techniques

(PB95-104485) Avail: Issuing Activity (National Technical Information Service (NTIS))

The study explored the possibility of producing laser oscillation through the action of metastable oxygen on heated metals. It attempted to reproduce the results of the YOSHIDA experiment, in which an iodine-oxygen chemical laser appeared to produce intense emissions in the visible (red and infrared) spectrum under certain conditions in the laser's reaction area. An extensive analysis of the YOSHIDA reaction enabled the authors to elucidate the main mechanisms of the red and infrared emissions. They were unable to reproduce the laser oscillations in the red region, and their study indicated little likelihood of that being possible, at least in continuous mode. On the other hand, the metastable state that causes infrared emission could be sustained in population inversion of the basic CuCl2 state, as long as the chemically-induced population of the electronic state was efficient enough. LASER-INDUCED THERMAL ACOUSTICS (LITA): FOUR-WAVE MIXING MEASUREMENT OF SOUND SPEED, THERMAL DIFFUSIVITY, AND VISCOSITY

Eric B. Cummings Aug. 1994 11 p Presented at the International Conference of Lasers (SOQUE), McLean, VA, 1993 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(Contract F49620-93-1-0338; AF Proj. 3484)

(AD-A286524; AFOSR-94-0738TR) Avail: CASI HC A03

Laser-induced thermal acoustics (LITA) is a promising optical four-wave mixing technique for gasdynamic measurement. The Chi(3) nonlinear process is a sequence of two opto-acoustic effects, electrostriction and absorption/rapid-thermalization, and the acousto-optic effect. The evolution of the laser-induced acoustic structures temporally modulates Chi(3) and thereby the LITA signal. Time resolution of the signal provides the sound speed, thermal diffusivity, and acoustic damping rate, along with information about atomic or molecular energy transfer rates. LITA can also measure spectra of both the real and imaginary gas susceptibility. The physics of LITA is discussed and the derivation is sketched of a simple analytical expression that accurately describes both the magnitude and time history of the LITA signal. Early experimental results are presented. Sound speeds accurate to 0.5% and transport properties accurate to 30% have been measured in a single-shot without calibration. More realistic modeling should dramatically improve transport-property measurement. LITA spectra have been taken of weak spectral lines of NO2 in concentrations less than 50 ppb. Signal reflectivities as high as 0.0001 have been estimated. New applications of LITA, including velocimetry, are suggested. DTIC

ULTRAVIOLET LASER EMISSION PROPERTIES OF Ce(3+)-DOPED LiSrAlF6

C. D. Marshall, S. A. Payne, J. A. Speth, W. F. Krupke, G. J. Quarles (Lightning Optical Corp., Tarpon Springs, FL.), V. Castillo (Lightning Optical Corp., Tarpon Springs, FL.), and B. H. T. Chai (University of Central Florida, Orlando, FL.) Mar. 1994 7 p Presented at the 9th Advanced Solid-State Lasers Meeting, Salt Lake City, UT, 7-10 Feb. 1994

(Contract W-7405-eng-48)

(DE94-016364; UCRL-JC-115148; CONF-940226-9) Avail: CASI HC A02/MF A01

The ultraviolet laser properties of Ce(3+)-doped LiSrAlF6 (Ce:LiSAF) and LiCaAlF6 (Ce:LiCAF) are reported. The polarized absorption, emission and excited state absorption cross sections for both Ce:LiSAF and Ce:LiCAF were determined for the 266 nm pump and 290 nm laser emission wavelengths. The gain was found to be highest when the probe was polarized parallel to the optic axis of the crystal due to the anisotropic nature of the excited state absorption. The excited state absorption is ascribed to a transition from the 5d orbital of Ce(3+) to the conduction band of the host. Laser slope efficiencies of up to 29% and 21% were measured for Ce-LiSAP and Ce:LiCAF when the 266 nm pulsed pump beam was polarized parallel to the optic axis. These are the highest laser slope efficiencies yet observed for any known solid-state ultraviolet laser material. DOE

Simplified analytic models for beam propagation in slab and bow-tie x ray lasers yield convenient expressions that provide both a framework for guidance in computer modeling and useful approximates for experimenters. In unrefracted bow-tie lasers, the laser shape in conjunction with the nearly-exponential weighting of rays according to their length produces a small effective aperture for the signal. We develop an analytic expression for the aperture and the properties of the far-field signal. Similarly, we develop the view that the far-field pattern of refractive slab lasers is the result of effective apertures that are created by the interplay of refraction and exponential amplification. We present expressions for the size of this aperture as a function of laser parameters as well as for the intensity and position of the far-field lineout. This analysis also yields conditions for the refraction limit in slab lasers and an estimate for the signal loss due to refraction. DOE

MECHANISMS AND DIAGNOSTICS OF ULTRASHORT PULSE LASER OCULAR EFFECTS Annual Technical Report, 15 Apr. 1993 - 14 Apr. 1994
James G. Fujimoto 30 Sep. 1994 12 p
(Contract F49620-93-1-0301)
(AD-A285610; AFOSR-94-0656TR) Avail: CASI HC A03/MF A01

The objective of our program is to investigate the mechanisms of ultrashort pulse laser retinal injury and to develop and apply new diagnostics for the assessment of retinal injury. During the past contract period, we have focussed on the development of a new diagnostic technique called optical coherence tomography (OCT) for the noninvasive measurement of ocular and retinal structure. EBIT X RAY SPECTROSCOPY STUDIES FOR APPLICATIONS TO PHOTO-PUMPED X RAY LASERS
S. R. Elliott, P. Beiersdorfer, and J. Nilsen 10 May 1994 7 p Presented at the 4th International Colloquium on X Ray Lasers, Williamsburg, VA, 16-20 May 1994
(Contract W-7405-eng-48)
(DE94-016701; UCRL-JC-116836; CONF-940592-5) Avail: CASI HC A02/MF A01

Several pumping mechanisms have been suggested for x-ray lasers including collisional excitation, recombination, photo-ionization and photo-pumping. The success of photo-pumping as an x-ray laser scheme hinges on sufficient overlap of the emission and adsorption lines. For such a scheme to exhibit gain, the difference of the energies of the two lines must be within the line widths determined by the plasma dynamics, such as Doppler and opacity broadening. Typically, an overlap of a few parts in 10(exp 4) is required. Due to correlation effects, high-n levels of multi-electron ions are difficult to calculate and are reliable to roughly a part in 10(exp 3). These differences are large enough to preclude accurate predictions of successful overlaps. As a result, precise measurements of the overlaps are needed. The continued interest in photo-pumping schemes lies in its potential to improve the laser output. It also allows the excitation of lasing transitions not accessible to other mechanisms and thus to the test laser kinetics from a different perspective. We have studied several such photo-pumping schemes at the LLNL electron beam ion trap. The N-like isoelectronic sequence 3d-5f and 3d-6f transitions were studied for photo-pumping by He-like ions, the Ne-like 2p-4d transitions were studied for photo-pumping by N-like 3d-4f transitions, and Ni-like 3d(sub 5/2)-6f(sub 7/2) transitions were studied for photo-pumping by H-like Ly-alpha transitions. A number of other chance coincidence pairs which do not follow an isoelectronic sequence were also studied. The data were taken with a flat-crystal vacuum spectrometer, a flat-crystal helium atmosphere spectrometer, or a curved-crystal spectrometer in the von Hamos geometry. The advantage of EBIT over laser-produced or tokamak plasmas for such experiments is its ability to control the charge balance and the excitation process. By choosing the electron beam energy, we can select a dominant charge state. DOE

LARGE FACILITIES PILOT PROGRAMME. ACCESS TO THE VULCAN HIGH POWER LASER FACILITIES AT RUTHERFORD APPLETON LABORATORY Final Technical Report
A. Giulietti, V. Biancalana, P. Chessa, D. Giulietti, and L. A. Gizzi Jun. 1994 19 p Prepared in cooperation with Institute of Atomic and Molecular Physics, Pisa, Italy; Ecole Polytechnique, Palaiseau, France; and Imperial Coll. of Science and Technology, London, England
(PB95-130340; RAL-94-060) Avail: Issuing Activity (National Technical Information Service (NTIS))

The funds allocated under this contract were used to operate the VULCAN 5 Terawatt Nd:Glass laser for a major experiment for which special configurations of the laser and diagnostic equipment were required. Complex targets were required, and a special fabrication process was developed. A wide variety of laser beam outputs were provided from Vulcan including beam smoothing by random phase plates (RPP), Induced Spatial Incoherence (ISI) and Smoothing by Spectral Dispersion (SSD). A pulse sequence from the laser was used to generate a pre-formed uniform plasma using four main beams, which was then heated by a delayed interaction beam. This arrangement simulates the plasma conditions of interest to I.C.F. studies. The interaction was studied by emission spectroscopy, and optical probing using a further synchronized laser beam. Optical streak cameras were used to observe the time dependence of spatial and spectral features of the plasma emission, and Nomarski interferometry was used to diagnose plasma density distribution as a function of time during the pulse. Time resolved X-ray diagnostics gave information on the plasma temperature. During four weeks of data taking, 180 full power shots were delivered to target (a record for a single experiment), and all the major objectives of the experiment were achieved. NTIS

Nuclear reactor-pumped lasers (RPL's) have been developed in the US by the Department of Energy for over two decades, with the primary research occurring at Sandia National Laboratories and Idaho National Engineering Laboratory. The US program has experimentally demonstrated reactor-pumped lasing in various mixtures of xenon, argon, neon, and helium at wavelengths of 585, 703, 725, 1,271, 1,733, 1,792, 2,032, 2,630, 2,650, and 3,370 nm with intrinsic efficiency as high as 2.5%. The major strengths of a reactor-pumped laser are continuous high-power operation, modular construction, self-contained power, compact size, and a variety of wavelengths (from visible to infrared). These characteristics suggest numerous applications not easily accessible to other laser types. The continuous high power of an RPL opens many potential manufacturing applications such as deep-penetration welding and cutting of thick structures, wide-area hardening of metal surfaces by heat treatment or cladding application, wide-area vapor deposition of ceramics onto metal surfaces, production of sub-micron sized particles for manufacturing of ceramics, and 3-D ceramic lithography. In addition, a ground-based RPL could beam its power to space for such activities as illuminating geosynchronous communication satellites in the earth's shadow to extend their lives, beaming power to orbital transfer vehicles, removing space debris, and providing power (from earth) to a lunar base during the long lunar night. SELF-STARTING FEMTOSECOND PULSE GENERATION FROM A TI:SAPPHIRE LASER SYNCHRONOUSLY PUMPED BY A POINTING-STABILIZED MODE-LOCKED Nd:YAG LASER

Craig W. Siders, Erhard W. Gaul, Michael C. Downer, Alexei Babine (Academy of Sciences, USSR, Nizhny Novgorod, USSR.), and Andrey Stepanov (Academy of Sciences, USSR, Nizhny Novgorod, USSR.) 1994 11 p Presented at the OE/LASE 1994: Conference on Optics, Electro-optics, and Laser Applications in Science and Engineering, Los Angeles, CA, 22-29 Jan. 1994
(Contract DE-FG05-92ER-40739)
(DE94-019319; CONF-940142-47) Avail: CASI HC A03/MF A01

We have constructed a self-starting Kerr-lens mode-locked Ti:sapphire laser pumped synchronously by a mode-locked, LBO-doubled Nd:YAG laser. Using a home-built beam-pointing stabilizer, beam wander of the 532 nm pump is reduced by a factor of 25, thus enabling long term operation of TEM(sub 00) nearly transform limited pulses with amplitude, repetition rate, and pulsewidth fluctuations comparable to or better than those of Ar-pumped Ti3(+):Al2O3 lasers. Interferometric autocorrelation using second harmonic in reflection from GaAs yielded a pulse width of 30 fs, limited by the dispersion of wide bandwidth cavity optics which permit tunability from 0.7 to 1.0 microns. TIME-RESOLVED STUDY OF SIDEBAND GENERATION AND TRANSITION TO CHAOS ON AN INFRARED FEL

W. P. Leemans, M. E. Conde, R. Govil, B. vanderGeer, M. deLoos, H. A. Schwettman (Stanford Univ., CA.), T. I. Smith (Stanford Univ., CA.), and R. L. Swent (Stanford Univ., CA.) Aug. 1994 12 p Presented at the 16th International Free Electron Laser Conference, Stanford, CA, 21-26 Aug. 1994
(Contract DE-AC03-76SF-00098)
(DE95-002336; LBL-36109; CBP-102; CONF-9408146-10) Avail: CASI HC A03/MF A01

We report observations on sideband generation and transition to chaos in an infrared Free Electron Laser operating at a wavelength (lambda)(sub r) of 4 micrometers with a low loss optical cavity. The temporal evolution of the radiation spectrum through the complete macropulse has been measured on a micropulse to micropulse basis. Stable sidebands are observed for small cavity detuning with frequency offsets in good agreement with calculations. For even smaller cavity detuning, self-oscillations occur with the main laser wavelength varying by up to 2%. Using a wavelength stabilization system based on RF feedback, we have suppressed these wavelength fluctuations without loss of peak power. DOE

LASER MATERIALS PROCESSING AT SANDIA NATIONAL LABORATORIES

James L. Jellison and Michael J. Cieslak 1994 10 p Presented at the Applications of Lasers and Electro-optics, Orlando, FL, 17-20 Oct. 1994
(Contract DE-AC04-94AL-85000)
(DE95-002183; SAND-94-2676C; CONF-9410189-5) Avail: CASI HC A02/MF A01

The interest in laser processing has been driven by Sandia's responsibility to design, prototype, manufacture, and steward high reliability defense hardware for the Department of Energy. The system requirements for the hardware generally necessitate hermetic sealing for ensured long life operation. With the advent of miniaturized electronic devices, traditional welding processes were no longer practical choices because of their limited ability to make very small weld closures without heat damage to the hardware. Gas and solid state lasers offered the opportunity to make hermetic closure welds in small, heat sensitive hardware. In order to consistently produce quality product, the Sandia laser materials processing team performed research aimed at identifying those critical parameters which controlled the laser welding process. This has been directed towards both the development of quantitative engineering data needed in product design and process control, and research to achieve fundamental process understanding. In addition, they have developed novel diagnostic systems to measure these important parameters, pioneered the use of calorimetric techniques to measure energy transfer efficiencies, and correlated the occurrence of welding defects with alloy compositions and type of laser welding process. Today, Sandia's laser materials processing team continues to advance the state of laser processing technology in many areas, including aluminum laser welding, the design of novel optics for specific laser processing needs, laser micromachining of silicon and diamond for microelectronics applications, and fluxless laser soldering. This paper will serve to highlight some examples of where Sandia has made contributions to the field of laser materials processing and will indicate the directions where they expect to focus their future efforts. COMPETITION BETWEEN ELECTROMAGNETIC MODES IN A FREE-ELECTRON MASER Final Technical Report, 1 Mar. 1990 - 28 Feb. 1994

Alan H. McCurdy, V. Kasibhotla, R. Liou, and J. S. Plewa 28 Feb. 1994 90 p
(Grant AF-AFOSR-0155-90)
(AD-A279546; AFOSR-94-0305TR) Avail: CASI HC A05/MF A01

A three part report is presented describing the mode competition in a gyrotron oscillator with two competing electromagnetic modes. Part 1 gives the theory of this mode coupling is presented using a quasi-linear assumption which is valid for small power levels. The results are interpreted in terms of the phase plane. These general results are applied to a specific case of mode competition, that between TE101 and TE011 modes in a cavity of rectangular cross section. Part 2 presents the theory of coupling which may occur between any number of cavity modes through finite conductivity in the cavity walls, holes in the conducting cavity walls, or though interaction with an electron beam. Part 3 details the experimental work. The electrodynamic circuit is described as are microwave and electron beam diagnostics. Results of initial tests are also given. DTIC

MOLECULAR DESIGN CONCEPT FOR MULTI-KILOVOLT X-RAY AMPLIFICATION

C. K. Rhodes, A. McPherson, and K. Boyer 24 May 1994 10 p
(Contract DE-FG02-91ER-12108)
(DE95-001763; DOE/ER-12108/T1) Avail: CASI HC A02/MF A01

The goal of this program is the construction of an X-ray laser in the multi-kilovolt regime which can serve as a vital enabling technology in the broad and fundamental field of materials science. Experimental findings indicate that an entirely new technique for amplification at X-ray wavelengths is feasible. This method involves the combination of: (1) a recently discovered mode of multiphoton coupling to molecules which efficiently yields core excited ions; (2) a new channeled mode of propagation for spatial organization; and (3) an ultrahigh brightness subpicosecond laser technology. The concept of molecular X-ray laser design, which involves matching the conditions of excitation to the molecular structure, enables the inner-shell excitation to be selectively achieved. Basically, the molecular approach enables the copious generation of a highly excited species to occur rapidly in an environment characteristic of dense cold matter, a situation exceptionally conducive to X-ray amplification. High energy efficiency and wavelength tunability also appear as intrinsic features of this method. Experimental data concerning the study of five cases (Xe(N), Xe(M), Xe(L), Kr(M), and Kr(L)), spanning-spectrally from approximately 80 eV to approximately 5 keV, have: (1) established the important role of cluster formation; (2) verified the scaling of this phenomenon into the kilovolt region; (3) demonstrated the production of hollow atoms having multiple inner-shell vacancies; (4) provided evidence for the crucial influence of coherent electronic motions on the strength of the multiphoton coupling; (5) led to the conclusion that a regime of strong-coupling exists in which multi-electron ejection from an inner-shell can occur with high probability; (6) revealed the scaling in atomic number which potently favors heavy atoms; and (7) combined the multiphoton induced X-ray emission from clusters with channeled propagation. DOE

DIRECTED LIGHT FABRICATION
G. K. Lewis, R. Nemec, J. Milewski, D. J. Thoma, D. Cremers, and M. Barbe 1994 11 p Presented at the Applications of Lasers and Electro-Optics, Orlando, FL, 17-20 Oct. 1994 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract W-7405-eng-36)
(DE94-018293; LA-UR-94-2845; CONF-9410189-2) Avail: Issuing Activity (Department of Energy (DOE))

Directed Light Fabrication (DLF) is a rapid prototyping process being developed at Los Alamos National Laboratory to fabricate metal components. This is done by fusing gas delivered metal powder particles in the focal zone of a laser beam that is programmed to move along or across the part cross section. Fully dense metal is built up a layer at a time to form the desired part represented by a 3 dimensional solid model from CAD software. Machine 'tool paths' are created from the solid model that command the movement and processing parameters specific to the DLF process so that the part can be built one layer at a time. The result is a fully dense, near net shape metal part that solidifies under rapid solidification conditions. DOE

METHOD FOR LASER-ASSISTED SILICON ETCHING USING HALOCARBON AMBIENTS Patent
Stephen D. Russell, inventor (to Navy), Douglas A. Sexton, inventor (to Navy), and Richard J. Orazi, inventor (to Navy) 20 Sep. 1994 22 p Filed 25 May 1993
(AD-D016494; US-Patent-5,348,609; US-Patent-Appl-SN-066745; US-Patent-Class-156-345) Avail: US Patent and Trademark Office

An etching process allows a selective single-step patterning of silicon devices in a noncorrosive environment. The etching of silicon relies on a maskless laser-assisted technique in a gaseous halocarbon ambient, such as the gaseous chlorofluorocarbons, dichlorodifluoromethane and chloropentafluoroethane. Laser-assisted photothermal chemical etching reactions on silicon occur in these ambients when the incident fluence from an excimer laser at 248 nm exceeds the melt threshold (approximately 0.75 J/sq cm). When incident fluence exceeds the ablation threshold (approximately 2.2 J/sq cm) an undesirable, increased surface roughness is observed. Etch rates as large as approximately 15 angstroms per pulse are attained within predetermined processing windows. This provides a means for thin membrane formation in silicon, rapid etches and processing of packaged devices or partially fabricated dies. The reduction in processing steps as compared to conventional wet chemical etches provides improvements in yield reliability and cost. DTIC

N95-21919# Los Alamos National Lab., NM.
PERFORMANCE OF CESIUM TELLURIDE PHOTOCATHODES AS AN ELECTRON SOURCE FOR THE LOS ALAMOS FEL
S. H. Kong, J. Kinross-Wright, D. C. Nuguyen, R. L. Sheffield, and M. E. Weber 1994 9 p Presented at the 16th International Free Electron Laser Conference, Stanford, CA, 21-26 Aug. 1994
(Contract W-7405-eng-36)
(DE94-018302; LA-UR-94-2850; CONF-9408146-3) Avail: CASI HC A02/MF A01

The Los Alamos Advanced Free Electron Laser (FEL) was successfully operated with a Cs2Te photocathode driven by a frequency quadrupoled Nd:YLF laser as the electron source. Lasing was achieved at 5-6 microns. Cs2Te photocathodes with quantum efficiencies of 12-18% at 254 nm were fabricated in an ultrahigh-vacuum chamber and transferred under high vacuum to the FEL. 263 nm light from the drive laser was focused to an 8 mm spot on the center of the photocathode. The authors estimated the operational life time of Cs2Te photocathodes to be at least 20 times that for K2CsSb photocathodes. The measured dark current of 0.3 mA in an electric field of 22-24 MV/m is well within the acceptable level. The maximum amount of charge extracted was observed to be limited by space charge to about 3.5 nC per micropulse. The emittance of the beam was estimated by fitting the data from a quadrupole scan. The authors measured an emittance that is comparable with the emittance measured with a K2CsSb photocathode in their system. A pulse length of 9.3 +/- 2 ps for 1.3 +/- 0.2 nC electron micropulses and a pulse length of 7.1 +/- 0.7 ps for the laser pulses were measured with a streak camera. Therefore, the response of the Cs2Te photocathode to the laser pulse is sufficiently fast for FEL applications. DOE

TUNABLE CW BLUE, GREEN, ORANGE AND RED UPCONVERSION FIBER LASERS AT ROOM TEMPERATURE
Ping Xie and T. R. Gosnell 1994 24 p Presented at the Annual Meeting of the Optical Society of America, Dallas, TX, 2-7 Oct. 1994
(Contract W-7405-eng-36)
(DE95-000851; LA-UR-94-3020; CONF-941062-1) Avail: CASI HC A03/MF A01

The authors report tunable CW laser actions at 491-493nm, 517-540nm, 605-622nm and 635-637nm in Pr(3+)/Yb(3+) doped ZBLAN optical fibers. A tunable Ti:Al2O3 laser was used as the pump source to simulate diode laser pumping. With 60 nW launched power, the excitation wavelength of the lasers was in the range of 780nm to 880nm. 300mW Output power has been achieved at 635nm with 760mW launched power at 860nm. With the pump wavelength at 860nm, the authors have also demonstrated stimulated emissions of 45mW at 615 nm with 430mW launched power, 20mW at 520 and 4mW at 493nm with 200mW launched power. DOE

N95-22079# New Energy and Industrial Technology Development Organization, Tokyo (Japan).
RESEARCH ON THE PROMOTION MEASURES TO INTRODUCE NEW ENERGY AND ENERGY-SAVING TECHNOLOGIES WITH A LEASING SYSTEM
Mar. 1994 111 p In JAPANESE
(DE95-714801; NEDO-P-9328) Avail: CASI HC A06/MF A02

Effects of introducing the leasing system were studied in order to promote the introduction of photovoltaic power generation, wind power generation and other new energy technologies, and phosphoric acid fuel cell, regional air conditioning and other energy efficiency-heightening technologies. Judging from the result of investigating its needs, the introduction of leasing system is most effective when the technological reliability and safety have been established with a cost differential made small, to a certain extent, from the existing energy. The introduction of leasing system is considered effective not from the point of view that, in order to reduce the initial introduction cost, the leasing system is the best measures of investment in the facilities for the introduction of new energy and energy-saving technologies, but from the point of view that the addition of leasing system as one of the preferential measures widens the user's selectivity among the debt, self-funds and leasing. The following tasks are raised for the introduction of leasing system: Determination of leasing term, Determination of insurance rate, Study of leasing for the household use, Development of leasing system as commodities fulfilling the user's needs. HIGH AVERAGE POWER DIODE PUMPED SOLID STATE LASERS FOR CALIOPE

B. Comaskey, J. Halpin, and B. Moran Jul. 1994 20 p Presented at the 1994 Chemical Analysis by Laser Interrogation of Proliferation Effluents (CALIOPE ITR) Interim Technical Review, Livermore, CA, 26-28 Apr. 1994
(Contract W-7405-eng-48)
(DE94-019248; UCRL-JC-118148; CONF-9404162-13) Avail: CASI HC A03/MF A01

Diode pumping of solid state media offers the opportunity for very low maintenance, high efficiency, and compact laser systems. For remote sensing, such lasers may be used to pump tunable nonlinear sources, or if tunable themselves, act directly or through harmonic crystals as the probe. The needs of long range remote sensing missions require laser performance in the several watts to kilowatts range. At these power performance levels, more advanced thermal management technologies are required for the diode pumps. The solid state laser design must now address a variety of issues arising from the thermal loads, including fracture limits, induced lensing and aberrations, induced birefringence, and laser cavity optical component performance degradation with average power loading. In order to highlight the design trade-offs involved in addressing the above issues, a variety of existing average power laser systems are briefly described. Included are two systems based on Spectra Diode Laboratory's water impingement cooled diode packages: a two times diffraction limited, 200 watt average power, 200 Hz multirod laser/amplifier by Fibertek, and TRW's 100 watt, 100 Hz, phase conjugated amplifier. The authors also present two laser systems built at Lawrence Livermore National Laboratory (LLNL) based on their more aggressive diode bar cooling package, which uses microchannel cooler technology capable of 100% duty factor operation. They then present the design of LLNL's first generation OPO pump laser for remote sensing. This system is specified to run at 100 Hz, 20 nsec pulses each with 300 mJ, less than two times diffraction limited, and with a stable single longitudinal mode. The performance of the first testbed version is presented. The authors conclude with directions their group is pursuing to advance average power lasers. This includes average power electro-optics, low heat load lasing media, and heat capacity lasers. DOE

RECENT PROGRESS OF THE COMPACT AFEL AT LOS ALAMOS

D. C. Nguyen, S. M. Gierman, J. C. Goldstein, J. M. Kinross-Wright, S. H. Kong, J. G. Plato, S. J. Russell, R. L. Sheffield, F. E. Sigler, and B. A. Sherwood et al 1994 16 p Presented at the 16th International Free Electron Laser Conference, Stanford, CA, 21-26 Aug. 1994
(Contract W-7405-eng-36)
(DE95-002728; LA-UR-94-3624; CONF-9408146-12) Avail: CASI HC A03/MF A01

The Advanced Free Electron Laser (AFEL) is a compact, infrared, RF-linac FEL that uses a high-brightness photoinjector and a short-period permanent-magnet wiggler. Lasing at saturation with and without sidebands has been achieved over the 4-6 micrometer region with a nominally 15-MeV electron beam energy and a 1-cm period, 24-period wiggler. Sideband-free FEL operation was optimized with respect to outcoupling by tuning off the reflectivity curve of the multilayer dielectric mirrors. Sideband operation was achieved using copper mirrors with a 1.1% outcoupling hole. The measured macropulse energy with (approximately)1300 micropulses was approximately 50 mJ per 1 nC of beam, corresponding to an output efficiency of 0.25% and a maximum extraction efficiency of 1.4%. INTERNATIONAL SYMPOSIUM ON ADVANCED LASER TECHNOLOGIES

13 Nov. 1993 133 p Sympoosium held in Prague, Czechoslovakia, 8-13 Nov. 1993 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract DAJA45-93-M-0461)
(AD-A279849; R/D-7234-EE-02) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Optical reflectivity and transmissivity measurements have been used to investigate the dynamics of melting and recrystallization of thin films of Si and Ge after laser-annealing with a ns Nd:YAG-laser pulse. We report on temperature dependent changes of the reflectivity of the liquid phase above and below the melting point and on various nucleation and solidification scenarios in thin films, depending on the energy density of the annealing laser. CRYOGENIC PELLET LASER PLASMA SOURCE TARGETS

Glenn D. Kubiak, Kevin D. Krenz, Kurt W. Berger, Timothy G. Trucano, Peter W. Fisher (Oak Ridge National Lab., TN.), and Michael J. Gouge (Oak Ridge National Lab., TN.) 1994 8 p Presented at the Optical Society of America Conference on Extreme Ultraviolet Lithography, Monterey, CA, 19-21 Sep. 1994 Sponsored by ARPA Advanced Lithography Program
(Contract DE-AC04-94AL-85000)
(DE95-002488; SAND-95-8426C; CONF-9409177-3) Avail: CASI HC A02/MF A01

We have developed a new laser plasma cryogenic target scheme that achieves high conversion efficiency (CE), but produces no condensable target debris and low vaporized target gas loads. This scheme employs a solidified pellet of a rare gas, such as Xe, which is irradiated in free flight by a focused drive laser. The pellet is made small enough that gas loads produced following target vaporization are manageable, but large enough to fully intercept the laser energy at its focus. To assess the fundamental utility of cryogenic pellet targets, we have examined the conversion efficiency, extreme ultraviolet (EUV) spectroscopy, and fragmentation dynamics of Xe pellets irradiated with a 248 mn KrF laser. PHOTOCATHODES FOR FREE ELECTRON LASERS

S. H. Kong, J. Kinross-Wright, D. C. Nuguyen, and R. L. Sheffield 1994 16 p Presented at the 16th International Free Electron Laser Conference, Stanford, CA, 21-26 Aug. 1994
(Contract W-7405-eng-36)
(DE94-018305; LA-UR-94-2849; CONF-9408146-5) Avail: CASI HC A03/MF A01

Many different photocathodes have been used as electron sources for Free Electron Lasers (FEL's) and other electron accelerator systems. In choosing one, a compromise between lifetime and quantum efficiency have been unavoidable. High quantum efficiency photocathodes such as CsK2Sb, Cs3Sb, and cesiated GaAs have short operational lifetimes and require an ultrahigh-vacuum environment. Long lifetime photocathodes such as LaB6, Cu, and Y have relatively low quantum efficiencies. However, recently, cesium telluride was found to be an exception. Initial results from CERN and now at Los Alamos have shown that Cs2Te is reasonably rugged with a high quantum efficiency below 270 nm. Further studies were carried out at Los Alamos in determining its performance as an electron source for the Los Alamos Advanced FEL. The Los Alamos Advanced FEL was successfully operated at 5-6 microns with a Cs2Te photocathode driven by a frequency quadrupoled Nd:YLF laser as the electron source. Cs2Te photocathodes with quantum efficiencies of 12-18% at 254 mn were fabricated in an ultrahigh-vacuum chamber and transferred under high vacuum to the FEL. The authors estimated that the operational lifetime of Cs2Te photocathodes to be at least 20 times that for K2CsSb photocathodes. Furthermore, experiments in the fabrication chamber have shown that heating to 150-200 C photocathodes exposed for one hour at 2 x 10(exp -4) torr of air was sufficient to revive the quantum efficiency from below 1% to about 10%. The electron beam for the FEL extracted from a cesium telluride target was also characterized. The emittance, response time, saturation level and dark current of cesium telluride photocathodes was determined to be sufficient for FEL applications. DOE

BROADBAND THERMAL OPTICAL LIMITER FOR THE PROTECTION OF EYES AND SENSORS Patent Application
Brian L. Justus, inventor (to Navy), Alan L. Huston, inventor (to Navy), and Anthony J. Campillo, inventor (to Navy) 31 May 1994 34 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-D016493; US-Patent-Appl-SN-251146) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

A broadband thermal optical limiter for protecting a light sensitive object from intense laser beams at all near ultraviolet, visible and near infrared wavelengths is disclosed. The broadband thermal optical limiter comprises: a sample cell containing a solution of broadband absorber material dissolved in a thermal solvent; and a first optical device for converging an incident laser beam into the sample cell. The sample cell is responsive to a converged incident laser beam below a predetermined intensity level for passing therethrough the converged incident laser beam below the predetermined intensity level. The sample cell is also responsive to a converged incident laser beam at or above a predetermined intensity level for thermally defocusing substantially all of the converged incident laser beam in different directions and passing therethrough only a remaining small portion of the converged incident laser beam at or above the predetermined intensity level. The broadband thermal optical limiter further includes a second optical device for focusing substantially all of the laser beam passing through the sample cell into the light sensitive object to be protected. COHERENCE PROPERTIES OF HIGH ORDER HARMONIC RADIATION
T. Ditmire, K. S. Budil, J. K. Crane, H. Nguyen, M. D. Perry, P. Salieres (Commissariat a l'Energie Atomique, Gif-sur-Yvette, France.), and A. L. Huillier (Commissariat a l'Energie Atomique, Gif-sur-Yvette, France.) May 1994 7 p Presented at the 9th International Conference on Ultrafast Phenomena, Dana Point, CA, 1-5 May 1994
(Contract W-7405-eng-48)
(DE94-016974; UCRL-JC-117330; CONF-940593-13) Avail: CASI HC A02/MF A01

The results of a series of experiments to characterize the coherence properties of XUV (extreme ultraviolet) radiation produced by high-order harmonic generation in helium, neon and argon are reported and compared to predictions from an effective order model. The harmonics exhibit smooth, near Gaussian spatial profiles, and have a divergence that is approximately constant (less than 12 mrad) in the plateau region and decreases (approximately 4 mrad) in the cutoff for f/17 focusing. For a bandwidth limited, 140 fsec incident pulse, we measure a harmonic line width of Delta lambda/lambda approximately 2 x 10(exp -3) at 30.3 nm. By reducing the spectral width of the driving pulse, harmonics with Delta lambda/lambda approximately 2 x 10(exp-4) can be produced. Absolute conversion efficiency as high as 10(exp -7) for harmonic radiation as short as 20 nm has been achieved by using 400 fsec, 526 nm pulses from an Nd:Glass laser. DOE

DEFECT GEOMETRIES AND LASER-INDUCED DAMAGE IN MULTILAYER COATINGS
R. J. Tench, M. R. Kozlowski, and R. Chow Jul. 1994 9 p Presented at the Annual Meeting of the Society of Photo-Optical Instrumentation Engineers, San Diego, CA, 24-29 Jul. 1994
(Contract W-7405-eng-48)
(DE94-017695; UCRL-JC-118203; CONF-940723-18) Avail: CASI HC A02/MF A01

A correlation between laser-induced damage and the height of a coating defect was found from an examination of HfO2/SiO2 mirrors made by three different coating vendors. The nodular defects in these reactive e-beam deposited mirrors were studied using the combination of SEM, optical microscopy, FIB and AFM techniques. Each vendor had small defects in common, but characteristically different large defects. Also the majority of seeds that caused the defects were made of hafnia, not silica. The apparent mechanical stability of the defects within the coating plays a major role in the laser resistance (1064 nm and 10ns) of a high damage threshold coating. DOE

FABRICATION AND CHARACTERIZATION OF CESIUM TELLURIDE PHOTOCATHODES: A PROMISING ELECTRON SOURCE FOR THE LOS ALAMOS ADVANCED FEL
S. H. Kong, D. C. Nuguyen, R. L. Sheffield, and B. A. Sherwood 1994 15 p Presented at the 16th International Free Electron Laser Conference, Stanford, CA, 21-26 Aug. 1994
(Contract W-7405-eng-36)
(DE94-018303; LA-UR-94-2851; CONF-9408146-4) Avail: CASI HC A03/MF A01

The Advanced Free Electron Laser (FEL) at Los Alamos embodies a K2CsSb photocathode as an electron source. The photocathode consists of a K2CsSb film deposited on a molybdenum plug that can be inserted into the linac of the FEL. However, because K2CsSb is easily contaminated and has a half-life of less than a day when in use, switching to a more rugged high quantum efficiency (QE) material such as Cs2Te is considered as a means to lengthen the beam time. Cs2Te films were deposited on molybdenum plugs in an ultrahigh-vacuum research chamber. Several Cs2Te films were measured in-situ for their spectral responses with a bias voltage of 90V; the resulting QE's were 12-18% at a wavelength of 254 nm, 0.2-1.2% at 334 nm, 10(exp -4)-10(exp -3) at 365 nm, and 10(exp -7)-10(exp -5) at 546 nm. For this cathode to be useful, the authors need to frequency quadruple the 1052 nm line of the Nd:YLF laser to achieve a wavelength of 263 nm. Initial studies showed that the 251-nm QE of Cs2Te is much less sensitive to contamination than the 526-nm QE of K2CsSb. The authors exposed Cs2Te photocathodes to air at 10(exp -4) torr for five minutes. As a result, the QE's dropped from 16-18% to 1-2% at 254 mn. However, heating the cathode to 165 C revived the QE to about 10%. They conclude that Cs2Te is a very rugged photocathode material for use in an RF photoelectron source. DOE

THE ORIGIN OF ACICULAR FERRITE IN GAS METAL ARC AND SUBMERGED ARC WELDS M.S. Thesis
Daniel G. Brothers Mar. 1994 161 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A286129) Avail: CASI HC A08

The nature of weld metal inclusions in relation to the formation of acicular ferrite was investigated. Gas-metal arc welds (GMAW) on High Strength Low Alloy (HSLA) plate with varying amounts of oxygen and/or carbon dioxide added to the argon cover gas and submerged arc welds (SAW) on HY-100 plate with five different fluxes were analyzed. This analysis determined the effect of weld metal composition on non-metallic inclusion composition and the ultimate effects on the formation of acicular ferrite. Scanning and transmission electron microscopy with energy dispersive x-ray analysis were used to determine inclusion size distribution, concentration and composition. This investigation revealed that the inclusions were complex MnO-Al2O3-SiO2-TiO2 oxides which contain a titanium-rich compound, Pyrophanite (MnTiO3), existing as a faceted particle in those inclusions promoting acicular ferrite formation. From these results and the research of others such as Grong/Matlock and Ramsay/Matlock/Olson it is concluded that the formation of acicular ferrite does depend on non-metallic inclusion composition demonstrating the importance of weld wire composition for achieving welds with optimum mechanical properties. APPLICATION OF A DIMENSIONLESS PARAMETER MODEL FOR LASER BEAM WELDING

P. W. Fuerschbach 1994 7 p Presented at the Applications of Lasers and Electro-Optics, Orlando, FL, 17-20 Oct. 1994
(Contract DE-AC04-94AL-85000)
(DE94-018902; SAND-94-1205C; CONF-9410189-4) Avail: CASI HC A02/MF A01

A new dimensionless parameter model for continuous wave laser welding that relates the size of the weld to the energy absorbed by the part is described. The model has been experimentally validated previously through calorimetric determinations of the net heat input and metallographic measurements of the weld size. It will be shown that both the melting efficiency and energy transfer efficiency for LBW are quite variable and need to be considered when selecting processing conditions. Specific applications will be detailed in order to observe the simplicity and value of the model in laser weld process development. It will be shown that by using certain dimensionless parameters one can determine the energy transfer efficiency and thereby correctly select processing conditions that more fully utilize the available laser output power. In applications where minimizing heat input to the surrounding weldment is paramount, the dimensionless parameters can be used to select conditions that maximize melting efficiency. DOE

FUSION WELDING OF ADVANCED BORATED STAINLESS STEELS

C. V. Robino and M. J. Cieslak Feb. 1994 85 p
(Contract DE-AC04-94AL-85000)
(DE94-019037; SAND-93-3981) Avail: CASI HC A05/MF A01

This work addressed two major areas concerning joining of advanced borated stainless steels. These areas included the development of a understanding of the physical metallurgy of borated stainless steels and the development of welding processes and post-weld heat treatments for these alloys. Differential thermal analysis experiments were conducted on ten heats of borated stainless steel to determine the transformation temperatures and melting behavior of the alloys. On-heating solidus temperatures were measured for all of the alloys and were used to define the temperatures associated with the fusion line during welding. Isothermal heat treatments designed to evaluate the effects of elevated temperature exposures on the toughness of the borated grades were conducted. These tests were used to determine if significant changes in the microstructure or mechanical properties of weld heat-affected zones (HAZ) occur. Specifically, the tests addressed the solid-state region of the HAZ. The test matrix included a variety of alloy compositions and thermal exposures at temperatures near the on-heating solidus (as determined by the DTA experiments). Welding experiments designed to assess the mechanical properties and microstructure of gas-tungsten arc and electron beam welds were conducted. DOE

BEVEL GEAR DRIVER AND METHOD HAVING TORQUE LIMIT SELECTION Patent Application

Joseph S. Cook, Jr., inventor (to NASA) 10 Aug. 1994 46 p
(NASA-Case-MSC-22384-1; NAS 1.71:MSC-22384-1;
US-Patent-Appl-SN-288102) Avail: CASI HC A03/MF A01

This invention comprises a torque drive mechanism utilizing axially translatable, mutually engageable transmission members having mating crown gears, driven and driving members with a three-element drive train being biased together by resilient means or by a fluid actuator system, the apparatus being operable to transmit a precisely controlled degree of torque to a driven member. The apparatus is applicable for use in hand tools and as a replacement for impact torque drivers, torque wrenches, motorized screw drivers, or the like, wherein the applied torque must be precisely controlled or limited. The bevel torque drive includes a drive gear which is axially displaceable and rotatable within cylindrical driver housing, a rotatable intermediate gear, and an output gear. Key rotationally secures displaceable gear with respect to input shaft but permits axial movement therebetween. A thrust bearing is preferably connected to the lower end of shaft for support to reduce play and friction between shaft and a transmission joint disc during rotation of the gear train. Coaxially mounted coiled spring is footed against displaceable gear for biasing the displaceable gear toward and into engagement with the intermediate gear for driving intermediate gear and output gear. Torque control is achieved by the use of straight or spiral beveled gears which are of configurations adapted to withdraw from mutual engagement upon the torque exceeding a predetermined limit. The novel, advantageous features of the invention include the configuration of the mating, crown gear sets and the axially translatable, slidable drive gear. The mechanism is capable of transmitting a high degree of torque within a narrow, compact transmission housing. The compact size and narrow, elongated configuration of the housing is particularly applicable for use in hand tools and in multiple torque driver mechanisms in which it is necessary to drive multiple fasteners which are located in close proximity. Prior torque drivers such as 'click-type' torque wrenches do not actually limit torque application but only provide an audible warning that the limit has been reached. Author

N95-20295 Department of the Navy, Washington, DC.

MALONE-BRAYTON CYCLE ENGINE/HEAT PUMP Patent

Thomas A. Gilmour, inventor (to Navy) 12 Jul. 1994 9 p Filed 28 Sep. 1993
(AD-D016573; US-Patent-5,327,745; US-Patent-Appl-SN-127567;
US-Patent-Class-62-467) Avail: US Patent and Trademark Office

A machine, such as a heat pump, and having an all liquid heat exchange fluid, operates over a more nearly ideal thermodynamic cycle by adjustment of the proportionality of the volumetric capacities of a compressor and an expander to approximate the proportionality of the densities of the liquid heat exchange fluid at the chosen working pressures. Preferred forms of a unit including both the compressor and the expander on a common shaft employs difference in axial lengths of rotary pumps of the gear or vane type to achieve the adjustment of volumetric capacity. Adjustment of the heat pump system for differing heat sink conditions preferably employs variable compression ratio pumps. DTIC

DISPLACEABLE SPUR GEAR TORQUE CONTROLLED DRIVER AND METHOD Patent Application

Joseph S. Cook, Jr., inventor (to NASA) 10 Aug. 1994 45 p
(NASA-Case-MSC-22381-1; NAS 1.71:MSC-22381-1;
US-Patent-Appl-SN-288112) Avail: CASI HC A03/MF A01

Methods and apparatus are provided for a torque driver including a laterally displaceable gear support member to carry an output spur gear. A biasing assembly biases the output spur gear into engagement with a pinion to which is applied an input torque greater than a desired output torque limit for a threaded fastener such as a nut or screw. A coiled output linkage connects the output spur gear with a fastener adaptor which may be a socket for a nut. A gear tooth profile provides a separation

force that overcomes the bias to limit torque at the desired torque limit. Multiple fasteners may be rotated simultaneously to a desired torque limit if additional output spur gears are provided. A gauged selector mechanism is provided to laterally displace multiple driver members for fasteners arranged in differing configurations. The torque limit is selectably adjustable and may be different for fasteners within the same fastener configuration.

CONCEPTUAL DESIGN OF AN RTG FACILITY TRANSPORTATION SYSTEM
Stephen J. Black, Robert C. Gentzlinger, and Richard E. Lujan 3 Jun. 1994 6 p Presented at the 12th Symposium on Space Nuclear Power and Propulsion, Albuquerque, NM, 8-12 Jan. 1995
(Contract W-7405-eng-36)
(DE94-014443; LA-UR-94-1938; CONF-950110-1) Avail: CASI HC A02/MF A01

The conceptual design of an Radioisotope Thermoelectric Generator (RTG) Facility Transportation System which is part of the overall RTG Transportation System has been completed and is described in detail. The Facility Transportation System serves to provide locomotion, cooling, shock protection and data acquisition for the RTG package during loading and unloading sequences. The RTG Facility Transportation System consists of a Transporter Subsystem, a Package Cooling Subsystem, and a Shock Limiting Transit Device Subsystem. The Transporter Subsystem is a uniquely designed welded steel cart combined with a pneumatically-driven hand tug for locomotion. The Package Cooling Subsystem provides five kilowatts of active liquid cooling via an on-board refrigeration system. The Shock limiting Transit Device Subsystem consists of a consumable honeycomb transit frame which provides shock protection for the 3855 kg (8500 LB) RTG package. These subsystems have been combined into an integrated system which will facilitate the unloading and loading of the RTG, of the Transport Trailer as well as meet ALARA radiation Package into and out exposure guidelines. DOE

INPUT SHAPING FOR VIBRATION-DAMPED SLEWING OF A FLEXIBLE BEAM USING A HEAVY-LIFT HYDRAULIC ROBOT
G. G. Parker, R. Eisler, J. Phelan, and R. D. Robinett 1994 8 p Presented at the 1994 American Control Conference, Baltimore, MD, 29 Jun. - 1 Jul. 1994
(Contract DE-AC04-94AL-85000)
(DE94-015803; SAND-94-1702C; CONF-9406133-3) Avail: CASI HC A02/MF A01

An input shaping scheme originally used to slew flexible beams via a tabletop D.C. motor is modified for use with an industrial-type, hydraulic-drive robot. This trajectory generation method was originally developed to produce symmetric, rest-to-rest maneuvers of flexible rotating rods where the angular velocity vector and gravitational vector were collinear. In that configuration, out-of-plane oscillations were excited due to centripetal acceleration of the rod. The bang-coast-bang acceleration profile resulted in no oscillations in either plane at the end of the symmetric slew maneuver. In this paper, a smoothed version of the bang-coast-bang acceleration is used for symmetric maneuvers where the angular velocity vector is orthogonal to the gravitational vector. Furthermore, the hydraulic robot servo dynamics are considered explicitly in determining the input joint angle trajectory. An instrumented mass is attached to the tip of a flexible aluminum rod. The first natural frequency of this system is about 1.0 Hz. Joint angle responses obtained with encoder sensors are used to identify the servo actuator dynamics.

USE OF AN INTEGRATED DESIGN TOOL FOR WELD QUALITY ENHANCEMENT
C. Cheng (Concurrent Technologies Corp., Johnstown, PA.), A. J. Paul (Concurrent Technologies Corp., Johnstown, PA.), and T. Zacharia 1993 8 p Presented at the American Welding Society International Conference on Modeling and Control of Joining Processes, Orlando, FL, 8-10 Dec. 1993
(Contract DE-AC05-84OR-21400)
(DE94-018135; CONF-931234-11) Avail: CASI HC A02/MF A01

It has been shown previously that the use of a mathematical model to predict the inherent fluid flow, heat transfer, free surface profiles and other associated phenomena during welding leads to a better understanding and, therefore, control of the welding process. Unfortunately many of the models available today are primarily research codes and, therefore, do not serve as design tools for the production welding engineer. In the current investigation, WELDER - a three dimensional, transient mathematical model, has been integrated with a framework based on the Rational Product & Process Design (R(center dot)P(sup 2)(center dot)D(sub sm))(sup +) methodology to create a true design tool aimed towards use by engineers. This highly interactive and graphic tool simulates the welding process from the start to finish, and provides the user with capabilities to view the progression of welding and the associated heating and cooling of the base plate. In addition, analysis modules analyze the temperature profiles to predict residual stresses and evolving microstructures. DOE

MODELING THE EFFECT OF SHROUD CONTACT AND FRICTION DAMPERS ON THE MISTUNED RESPONSE OF TURBOPUMPS Final Report, 31 May 1991 - 31 Aug. 1994
Jerry H. Griffin and M.-T. Yang Jan. 1994 79 p
(Contract NAS8-38348)
(NASA-CR-197285; NAS 1.26:197285) Avail: CASI HC A05/MF A01

The contract has been revised. Under the revised scope of work a reduced order model has been developed that can be used to predict the steady-state response of mistuned bladed disks. The approach has been implemented in a computer code, LMCC. It is concluded that: the reduced order model displays structural fidelity comparable to that of a finite element model of an entire bladed disk system with significantly improved computational efficiency; and, when the disk is stiff, both the finite element model and LMCC predict significantly more amplitude variation than was predicted by earlier models. This second result may have important practical ramifications, especially in the case of integrally bladed disks. Author

ABRASIVE WEAR BY DIESEL ENGINE COAL-FUEL AND RELATED PARTICLES
L. K. Ives Sep. 1994 66 p Sponsored in part by ORNL
(Contract DE-A105-83OR-21322)
(PB95-104915; NISTIR-5461; ORNL/SUB/83-21322/03) Avail: CASI HC A04/MF A01

The purpose of the work summarized in this report was to obtain a basic understanding of the factors which are responsible for wear of the piston ring and cylinder wall surfaces in diesel engines utilizing coal-fuel. The approach included analytical studies using scanning electron microscopy and energy dispersive x-ray analyses to characterize coal-fuel and various combustion particles, and two different wear tests. The wear tests were a modified pin-on-disk test and a block-on-ring test capable of either unidirectional or reciprocating-rotational sliding. The wear tests in general were conducted with mixtures of the particles and lubricating oil. The particles studied included coal-fuel, particles resulting from the combustion of coal fuel, mineral matter extracted during the processing of coal, and several other common abrasive particle types among which quartz was the most extensively examined. The variables studied included those associated with the particles, such as particle type, size, and hardness; variables related to contact conditions and the surrounding environment; and variables related to the type and properties of the test specimen materials. ELECTRORHEOLOGY FOR SMART AUTOMOTIVE SUSPENSIONS Final Technical Report
Z. Lou, C. B. Winkler, R. D. Ervin, F. E. Filisko, and P.J. Venhovens Jun. 1994 140 p
(Contract DAAE07-92-C-R078)
(AD-A285543; UMTRI-94-15) Avail: CASI HC A07/MF A02

The purpose of the work reported was to demonstrate the suitability of electrorheological (ER) technology for adaptive control of suspension forces on tracked and wheeled vehicles. The mechanical shear strength properties of ER fluids change in response to the application of an electric field. The change is very rapid and fully reversible. This property was used to create an automotive suspension damper whose resistive force is readily controlled by an external electrical signal. The device was applied in a semiactive suspension system for the Army's high mobility multipurpose wheeled vehicle (HMMWV). The work reported covers a range of development tasks including definition of the semiactive control algorithm, ER fluid formulation, design and fabrication of an ER damper, design of an electrical control circuit, creation of a quarter-HMMWV test stand for the simulation of ride vibrations, laboratory measurement of the ER-damped performance characteristics over a range of physically simulated operating conditions, and computer simulation of the quarter-HMMWV system. The research demonstrated that an ER damper and appropriate control circuits could out-perform the conventional hydraulic shock absorber, but that various complexities tend to impede broad application of electrorheology in automotive devices. PROCEEDINGS OF THE NATO-ADVANCED STUDY INSTITUTE ON COMPUTER AIDED ANALYSIS OF RIGID AND FLEXIBLE MECHANICAL SYSTEMS. VOLUME 1: MAIN LECTURES
Manuel S. Pereira, ed. and Jorge A. C. Ambrosio, ed. 9 Jul. 1993 493 p Meeting held in Troia, Portugal, 27 Jun. - 9 Jul. 1993
(Contract DAJA45-93-M-0233)
(AD-A286062; R/D-7022-MA-02-Vol-1) Avail: CASI HC A21/MF A04

During the last few years, major scientific progress has been achieved in fields related to computer aided analysis of multibody systems. In view of this progress and recent developments of computer hardware and general purpose software, there is a need to access the current state of art and results from different schools of thought, with the objective of focussing trends in future research. Going back to 1983 when an important NATO-NSF-ARO Advanced Study Institute on Computer Aided Analysis and Optimization of Mechanical Systems was held at the University of Iowa, one may notice that less then 10 years ago the state of art was mainly dwelling on rigid body dynamics. The interest in the dynamic simulation of mechanical systems has steadily increased in recent years coming mainly from the aerospace and automative industries. The development of multibody system analysis formulations have been more recently motivated with the need to include several features such as: real-time simulation capabilities, highly non-linear control devices, work space path planing, active control of machine flexibilities and reliability and accuracy in the analysis results. The need for accurate and efficient analysis tools for design of large and lightweight mechanical systems has driven many research groups in the challenging problem of flexible systems with an increasing interaction with finite element methodologies. Basic approaches to mechanical systems dynamic analysis have recently been presented in several new text books. These publications demonstrate that both recursive and absolute methods still have their proponents to resolve the redundancy encountered in most mechanical systems. DTIC

REDUCING EXHAUST GAS EMISSIONS FROM CITYDIESEL BUSSES Final Report
Seppo Mikkonen 1994 20 p In FINNISH
(DE95-700245; NEI-FI-234) Avail: CASI HC A03/MF A01

The effect of fuel composition and exhaust gas aftertreatment on the emissions was measured from truck and bus engines. Possibilities to measure unregulated emissions (aldehydes, polyaromatic hydrocarbons, mutagenicity) were built. A reformulated diesel fuel 'Citydiesel' was developed. Citydiesel was able to reduce emissions compared to standard diesel fuel as follows: particulates by 10 to 30%, nitrogen oxides by 2 to 10%, sulphur dioxide by 97%, polyaromatic hydrocarbons (PAH) over 50%, mutagenicity of the exhaust particulates clearly, odor of the exhaust, and smoke after a cold start. The use of Citydiesel fuel reduces emissions of the existing vehicles immediately which is a remarkable benefit. The very low sulphur content (below 50 ppm) makes it possible to use oxidation. catalytic converters to reduce emissions of diesel vehicles. The new Euro 2 exhaust regulations coming into force during 1996 can be met with a modern diesel engine, Citydiesel fuel, and exhaust gas aftertreatment. Properties of Citydiesel fuel were verified in a three year field test with 140 city buses. Experience was good; e.g., engine oil change interval could be lengthened. Total value of the exhaust was estimated with different fuels and aftertreatment device in order to find out cheap ways to reduce emissions. DOE

SEEK: A FORTRAN OPTIMIZATION PROGRAM USING A FEASIBLE DIRECTIONS GRADIENT SEARCH Final Report
M. Savage Cleveland, OH NASA Jan. 1995 149 p
(Grant NAG3-1047; RTOP 505-62-36; DA Proj. 1L1-62211-A-47-A)
(NASA-CR-4641; E-9338; NAS 1.26:4641; ARL-TR-645) Avail: CASI HC A07/MF A02

This report describes the use of computer program 'SEEK' which works in conjunction with two user-written subroutines and an input data file to perform an optimization procedure on a user's problem. The optimization method uses a modified feasible directions gradient technique. SEEK is written in ANSI standard Fortran 77, has an object size of about 46K bytes, and can be used on a personal computer running DOS. This report describes the use of the program and discusses the optimizing method. The program use is illustrated with four example problems: a bushing design, a helical coil spring design, a gear mesh design, and a two-parameter Weibull life-reliability curve fit. Author

JOINING OF DISSIMILAR MATERIALS. A REVIEW
Zheng Sun and Risto Karppi Mar. 1994 60 p
(ISSN 1235-0605)
(PB95-132999; VTT/RN-1545,; ISBN-951-38-4479-X) Copyright Avail: Issuing Activity (National Technical Information Service (NTIS))

Multimaterial technology is set to become one of the most promising solutions for the design and fabrication of many high performance products and engineering structures. Joining dissimilar materials is a key process in the manufacture of multimaterial products and has hence become a very important and vital field of research and development. This report contains a literature survey on the joining of dissimilar materials. The characteristics of dissimilar material joints are discussed. Theoretical and practical problems encountered in joining dissimilar materials are reviewed with special reference to the joinability of various materials and how they can be combined. Applications of dissimilar material joints are highlighted with reference to industrial requirements. Furthermore, examples are given in order to illustrate the principles of solving specific problems. The survey aims at providing the industrial and research and development (R&D) sectors with identification of the major needs for future development in the joining of dissimilar materials. NTIS

A series of studies was carried out to examine the weldability and properties of dissimilar steel joints between martensitic and austenitic stainless steels - F6NM (OCr13Ni4Mo) and AISI 347, respectively. Such joints are important parts in, e.g. the primary circuit of a pressurized water reactor (PWR). This kind of joint requires both good mechanical properties, corrosion resistance and a stable magnetic permeability besides good weldability. The weldability tests included weld thermal simulation of the martensitic steel for investigating the influence of weld thermal cycles and post-weld heat treatment (PWHT) on the mechanical properties of the heat-affected zone (HAZ); implant testing for examining the tendency for cold cracking of martensitic steel; rigid restraint testing for determining hot crack susceptibility of the multi-pass dissimilar steel joints. The joints were subjected to various mechanical tests including a tensile test, bending test and impact test at various temperatures, as well as slow strain-rate test for examining the stress corrosion cracking tendency in the simulated environment of a primary circuit of a PWR. The results of various tests indicated that the quality of the tube/tube joints is satisfactory for meeting all the design requirements. NTIS

WELD POOL PHENOMENA
S. A. David, J. M. Vitek, T. Zacharia, and T. DebRoy (Pennsylvania State Univ., University Park, PA.) 1994 29 p Presented at the 46th Annual Meeting of the International Institute of Welding (IIW), Glasgow, Scotland, 28 Aug. - 4 Sep. 1993
(Contract DE-AC05-84OR-21400)
(DE94-018965; CONF-9308247-1) Avail: CASI HC A03/MF A01

During welding, the composition, structure and properties of the welded structure are affected by the interaction of the heat source with the metal. The interaction affects the fluid flow, heat transfer and mass transfer in the weld pool, and the solidification behavior of the weld metal. In recent years, there has been a growing recognition of the importance of the weld pool transport processes and the solid state transformation reactions in determining the composition, structure and properties of the welded structure. The relation between the weld pool transport processes and the composition and structure is reviewed. Recent applications of various solidification theories to welding are examined to understand the special problems of weld metal solidification. The discussion is focussed on the important problems and issues related to weld pool transport phenomena and solidification. Resolution of these problems would be an important step towards a science based control of composition, structure and properties of the weld metal. DOE

ON THE ORIGINS AND MODELING OF FRICTIONAL BEHAVIOR IN INTERFACIALLY-COMPLEX SLIDING CONTACTS
P. J. Blau 1994 18 p Presented at the American Society of Mechanical Engineers/Society of Tribologists and Lubrication Engineers (ASME/STLE) Joint Tribology Conference, New Orleans, LA, 24-27 Oct. 1993
(Contract DE-AC05-84OR-21400)
(DE94-019129; CONF-9310170-2) Avail: CASI HC A03/MF A01

The magnitude of the kinetic friction force usually varies with time in very clean or marginally-lubricated sliding systems. In some poorly-lubricated tribosystems, this variation can be as large as the nominal value of the friction force itself. Most classical sliding friction models attempt to derive a single value for the friction force or friction coefficient for a given set of materials and conditions, even in the face of numerous experiments and observations of real machine behavior which continue to demonstrate its multivalued, time-dependent nature. The simultaneous frictional processes in complex sliding interfaces are considered in more detail using graphical constructions called friction process diagrams (FPD). These diagrams provide a straightforward technique to account for the changing, relative contributions of mechanisms which explain the variability in friction. Applications of binary and ternary FPD's to metallic and ceramic sliding systems with debris are provided to illustrate their wide applicability. DOE

MODELING OF ROLLING ELEMENT BEARING MECHANICS. COMPUTER PROGRAM USER'S MANUAL Final Report
Lyn M. Greenhill and David H. Merchant 1 Oct. 1994 65 p
(Contract NAS8-38607)
(NASA-CR-196557; NAS 1.26:196557) Avail: CASI HC A04/MF A01

This report provides the user's manual for the Rolling Element Bearing Analysis System (REBANS) analysis code which determines the quasistatic response to external loads or displacement of three types of high-speed rolling element bearings: angular contact ball bearings, duplex angular contact ball bearings, and cylindrical roller bearings. The model includes the defects of bearing ring and support structure flexibility. It is comprised of two main programs: the Preprocessor for Bearing Analysis (PREBAN) which creates the input files for the main analysis program, and Flexibility Enhanced Rolling Element Bearing Analysis (FEREBA), the main analysis program. This report addresses input instructions for and features of the computer codes. A companion report addresses the theoretical basis for the computer codes. REBANS extends the capabilities of the SHABERTH (Shaft and Bearing Thermal Analysis) code to include race and housing flexibility, including such effects as dead band and preload springs. Author

ATTACHMENT METHODOLOGY FOR COMPOSITE CYLINDER ASSEMBLY Patent
Roger M. Crane, inventor (to Navy) and Paul Coffin, inventor (to Navy) 22 Feb. 1994 10 p Filed 7 Apr. 1992
(AD-D016256; US-Patent-5,288,114; US-Patent-Appl-SN-864794; US-Patent-Class-285-370) Avail: US Patent and Trademark Office

Cylinder-to-cylinder attachment method and construction featuring nonutilization of mechanical fasteners or bonding, especially advantageous for attachment of cylinders which are composite or to be subjected to hydrostatic pressure, is described. A fastening ring is interpositionally and rotatively engaged and aligned with a toothed axial end of each cylinder whereby the inwardly radial teeth for each cylinder appropriately mesh with the outer grooved circumferential surface of the fastening ring. The resultant joint is easily detachable and less susceptible than conventional joints to damage, breakage, degradation, stress concentrations, and fluid infiltration. DTIC

Recent advances in the mathematical modeling of fundamental phenomena in welds are summarized. State-of-the-art mathematical models, advances in computational techniques, emerging high-performance computers, and experimental validation techniques have provided significant insight into the fundamental factors that control the development of the weldment. The current status and scientific issues in the areas of heat and fluid flow in welds, heat source metal interaction, solidification microstructure, and phase transformations are assessed. Future research areas of major importance for understanding the fundamental phenomena in weld behavior are identified. DOE

LOW ROTATIONAL DRAG IN HIGH-TEMPERATURE SUPERCONDUCTING BEARINGS
J. R. Hull, T. M. Mulcahy, K. L. Uherka, and R. G. Abboud (Commonwealth Research Corp., Chicago, IL.) 17 Oct. 1994 5 p Presented at the Applied Superconductivity Conference, Boston, MA, 16-21 Oct. 1994
(Contract W-31-109-eng-38)
(DE95-002983; ANL/ET/CP-82119; CONF-941013-8) Avail: CASI HC A01/MF A01

Bearings consisting of permanent magnets stably levitated over high-temperature superconductors exhibit low rotational drag and have the potential to enable high-efficiency flywheel energy storage. The coefficient of friction mu for such storage systems is derived as a function of bearing parameters and is shown to be an appropriate figure of merit to describe bearing losses. Analysis shows that values of mu 10(exp -6) enable flywheel standby losses less than 0.1 %/hr for high-speed flywheels. A vacuum-chamber experimental apparatus has been constructed to measure values of (mu) for various experimental bearing designs. Experimental values for mu at low velocity have been as low as 3 x 10(exp-7) for a 89-mm-diameter ring permanent magnet stably levitated over an array of melt-textured Y-Ba-Cu-O. An important loss mechanism occurs from eddy currents induced in the rotating magnet due to the discrete nature of the superconductor array. DOE

WELDING TRITIUM EXPOSED STAINLESS STEEL
W. R. Kanne, Jr. 1994 12 p Presented at the 5th International Conference on Hydrogen Effects on Material Behavior, Moran, WY, 11-15 Sep. 1994
(Contract DE-AC09-89SR-18035)
(DE95-003208; WSRC-MS-94-0101P; CONF-940945-4) Avail: CASI HC A03/MF A01

Stainless steels that are exposed to tritium become unweldable by conventional methods due to buildup of decay helium within the metal matrix. With longer service lives expected for tritium containment systems, methods for welding on tritium exposed material will become important for repair or modification of the systems. Solid-state resistance welding and low-penetration overlay welding have been shown to mitigate helium embrittlement cracking in tritium exposed 304 stainless steel. These processes can also be used on stainless steel containing helium from neutron irradiation, such as occurs in nuclear reactors. DOE

WAVE JOURNAL BEARING. PART 1: ANALYSIS Final Report
Florin Dimofte Cleveland, OH NASA Jan. 1995 10 p Presented at the Energy and Environmental Expo 1995, Houston, TX, 29 Jan. - 1 Feb. 1995; sponsored by ASME
(Grant NAG3-1370; RTOP 778-32-21)
(NASA-CR-195431-Pt-1; E-9423-Pt-1; NAS 1.26:195431-Pt-1) Avail: CASI HC A02/MF A01

A wave journal bearing concept features a waved inner bearing diameter of the non-rotating bearing side and it is an alternative to the plain journal bearing. The wave journal bearing has a significantly increased load capacity in comparison to the plain journal bearing operating at the same eccentricity. It also offers greater stability than the plain circular bearing under all operating conditions. The wave bearing's design is relatively simple and allows the shaft to rotate in either direction. Three wave bearings are sensitive to the direction of an applied stationary side load. Increasing the number of waves reduces the wave bearing's sensitivity to the direction of the applied load relative to the wave. However, the range in which the bearing performance can be varied decreases as the number of waves increases. Therefore, both the number and the amplitude of the waves must be properly selected to optimize the wave bearing design for a specific application. It is concluded that the stiffness of an air journal bearing, due to hydrodynamic effect, could be doubled and made to run stably by using a six or eight wave geometry with a wave amplitude approximately half of the bearing radial clearance. Author

WAVE JOURNAL BEARING. PART 2: EXPERIMENTAL PRESSURE MEASUREMENTS AND FRACTIONAL FREQUENCY WHIRL THRESHOLD FOR WAVE AND PLAIN JOURNAL BEARINGS
James F. Walker, Florin Dimofte (Toledo Univ., OH.), and Harold E. Addy, Jr. Jan. 1995 10 p Presented at the Energy and Environmental Expo 1995, Houston, TX, 29 Jan. - 1 Feb. 1995; sponsored by ASME
(Grant NAG3-1370; RTOP 778-32-21)
(NASA-TM-106848-Pt-2; E-9424-Pt-2; NAS 1.15:106848-Pt-2) Avail: CASI HC A02/MF A01

A new hydrodynamic bearing concept, the wave journal bearing, is being developed because it has better stability characteristics than plain journal bearings while maintaining similar load capacity. An analysis code to predict the steady state and dynamic performance of the wave journal bearing is also part of the development. To verify numerical predictions and contrast the wave journal bearing's stability characteristics to a plain journal bearing, tests were conducted at NASA Lewis Research Center using an air bearing test rig. Bearing film pressures were measured at 16 ports located around the bearing circumference at the middle of the bearing length. The pressure measurements for both a plain journal bearing and a wave journal bearing compared favorably with numerical predictions. Both bearings were tested with no radial load to determine the speed threshold for self-excited fractional frequency whirl. The plain journal bearing started to whirl immediately upon shaft start-up. The wave journal did not incur self-excited whirl until 800 to 900 rpm as predicted by the analysis. Furthermore, the wave bearing's geometry limited the whirl orbit to less than the bearing's clearance. In contrast, the plain journal bearing did not limit the whirl orbit, causing it to rub. Author

EDDY CURRENT FOR DETECTING SECOND-LAYER CRACKS UNDER INSTALLED FASTENERS Final Report, 30 Sep. 1991 - 31 Oct. 1993
Gary L. Buckhardt, Robert E. Beissner, Edith A. Creek, and Jay L. Fisher Feb. 1994 110 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract F33615-91-C-5661)
(AD-A279871; SWRI-17-4665; WL-TR-93-4125) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Southwest Research Institute developed an eddy current (EC) laboratory breadboard inspection system to detect second-layer cracks around installed fasteners in two-layer airframe structures with the probe positioned on the first layer (outside surface). Probe design considered both cup and segment-core configurations as exciter coils and various orientations and positions of sensor coils. Highest sensitivity was obtained with a segment-core exciter covering an 85 degree segment with the sensor oriented normal to the specimen surface and placed near the core outer leg. EC data were presented in two-dimensional color images. The goal of detecting a 2.5mm second-layer flaw through a first-layer thickness of 6.4mm was achieved in eight of nine specimen configurations which contained simulated cracks. The specimens included structure geometries containing second-layer edges, first-layer edges, adjacent fasteners, different fastener sizes, different flaw orientations around the hole, and fasteners of different materials (titanium and steel). In fatigue crack specimens supplied by WL/MLLP, where adjacent fasteners were spaced more closely and caused interfering signals, flaw detection was more difficult; however, a

2.5mm flaw was detected through a 4.5mm first layer by comparing the signal patterns from adjacent holes. DTIC

APPARATUS AND METHOD FOR DETERMINING THE MASS DENSITY OF A FILAMENT Patent Application
Jeffrey A. Hinkley, inventor (to NASA) and Joseph M. Marchello, inventor (to NASA) (Old Dominion Univ., Norfolk, VA.) 29 Sep. 1994 17 p
(Grant NAG1-1067)
(NASA-Case-LAR-14879-1-CU; NAS 1.71:LAR-14879-1-CU; US-Patent-Appl-SN-316708) Avail: CASI HC A03/MF A01

A method and apparatus for determining the mass density of a moving filament is provided. The method includes the steps of providing a filament across two supports, tensioning the filament, inducing a vibration into the filament segment between the supports, reinforcing the vibration using an amplified feedback signal, detecting the vibrational frequency data, processing the data using a fast-fourier transform analysis, and then displaying the frequency. The use of the feedback signal results in a self-tuning resonant loop. Open loop versions may also be used. The apparatus includes a base supporting a fixed support and a transducer which in turn supports a moveable support. The transducer vibrates the moveable support transversely to the direction of travel of the filament, thereby inducing a transverse vibrational mode. The output of the transducer is amplified and used to drive a second amplifier to produce a self-tuning resonant loop. In the open loop version a signal generator is used to drive the transducer through a frequency range, during which the amplitude peak is identified. NASA

Simpson, inventor (to NASA) (Lockheed Engineering and Sciences Co., Hampton, VA.), and Min Namkung, inventor (to NASA) 22 Nov. 1994 34 p Continuation-in-part of US-Patent-Appl-SN-134444, filed 12 Oct. 1993
(NASA-Case-LAR-15231-1-SB; NAS 1.71:LAR-15231-1-SB; US-Patent-Appl-SN-343740; US-Patent-Appl-SN-134444) Avail: CASI HC A03/MF A01

A flux-focusing electromagnetic sensor which uses a ferromagnetic flux-focusing lens simplifies inspections and increases detectability of fatigue cracks about circular fasteners and other circular inhomogeneities in high conductivity material. The unique feature of the device is the ferrous shield isolating a high-turn pick-up coil from an excitation coil. The use of the magnetic shield is shown to produce a null voltage output across the receiving coil in the presence of an unflawed sample. A redistribution of the current flow in the sample caused by the presence of flaws, however, eliminates the shielding condition and a large output voltage is produced, yielding a clear unambiguous flaw signal. By rotating the probe in a path around a circular fastener such as a rivet while maintaining a constant distance between the probe and the center of a rivet, the signal due to current flow about the rivet can be held constant. Any further changes in the current distribution, such as due to a fatigue crack at the rivet joint, can be detected as an increase in the output voltage above that due to the flow about the rivet head. (AD-A279407; WL-TR-94-5008) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This report describes the results of Phase 1 of the Infrastructure for KGD program at MCC. The objective of the work is to resolve the issues for supplying and procuring Known Good Die (KGD) in a way that fosters industry acceptance and confidence in Application Specific Electronic Modules (ASEM's for military systems) and MultiChip Modules (MCM's for commercial systems). This report is divided into four sections. Section 1 describes the technical assessment of proposed industry approaches to KGD implementation. Section 2 of the report contains an outline for the plan for industry and government cooperation for the demonstration, validation, and implementation of KGD methodologies identified in this Phase 1 study. Section 3 of the report contains the industry-generated requirements for KGD implementation. Section IV of the report contains the KGD specifications for TAB and flip chip IC's. DTIC

MINIMAX OPTIMAL STOP RULE IN RELIABILITY CHECKING
Jose M. Gouweleeuw 10 Mar. 1994 25 p Sponsored by Fulbright scholarship
(PB95-134557) Avail: CASI HC A03/MF A01

Consider a machine, that may or may not have a defect, and the probability q that this machine is defective is unknown. In order to determine whether the machine is defective, it is tested. On each test, the defect is found with probability p, if it has not been found yet. Performing n tests costs c(sub n) dollars. There is a fine of 1 dollar, if there is a defect and it is not found on the tests. When should we stop testing, in order to minimize the costs. This problem is treated in a minimax setting: the authors try to find a strategy that works well, even for 'bad' q's. It turns out that the minimax optimal stop rule can be unexpectedly complicated. For example, if p = 1/2 and c(sub n) = cn = 0.25n, then the optimal rule is to perform one test. If a defect is found, then again stop, else toss a coin and stop if this shows heads. If the authors have not stopped, a third and last test is performed. NTIS

EVALUATION OF SCANNERS FOR C-SCAN IMAGING FOR NONDESTRUCTIVE INSPECTION OF AIRCRAFT Final Report
John H. Gieske Sep. 1994 52 p
(Contract DTFA03-91-A-0018)
(AD-A286398; DOT/FAA/CT-94/79) Avail: CASI HC A04/MF A01

The goal of this project was to produce a document that contains information on the usability and performance of commercially available, fieldable, and portable scanner systems as they apply to aircraft nondestructive inspections. In particular, the scanners are used to generate images of eddy current, ultrasonic, or bond tester inspection data. The scanner designs include manual scanners, semiautomated scanners, and fully automated scanners. A brief description of the functionality of each scanner type, a sketch, and a list of the companies that support the particular design are provided. Vendors of each scanner type provided hands-on demonstrations of their equipment on aircraft samples in the Federal Aviation Administration (FAA) Aging Aircraft Nondestructive Inspection Validation Center in Albuquerque, New Mexico. From evaluations recorded during the demonstrations, a matrix of scanner features and factors and ranking of the capabilities and limitations of the design, portability, articulation, performance, usability, and computer hardware/software was constructed to provide a quick reference to compare the different scanner types. Illustrations of C-scan images obtained during the demonstration are shown. DTIC

ANALYSES OF SOME BENCHMARK CASES IN FRACTURE MECHANICS USING BOUNDARY ELEMENT METHOD
J. Tuhkuri 31 May 1994 50 p
(PB95-110888; ISBN-951-22-2162-4) Avail: CASI HC A03/MF A01

The boundary element method and especially the analysis of fracture mechanics problems by using the dual boundary element program Cracker is introduced. This code is especially suitable for studying crack growth in two-dimensional, linear, and elastic problems. Cracker can automatically model an incremental crack extension, and no user made remeshing is needed. Eleven different benchmark cases have been analyzed to verify the results given by Cracker. The stress intensity factors and the crack paths calculated by the program are similar to those given in the literature. NTIS

INELASTIC BENDING AND TORSION OF STEEL I-BEAMS
Y. L. Pi and N. S. Trahair Nov. 1993 38 p See also PB94-208360
(PB94-208378; R-683) Avail: CASI HC A03/MF A01

The inelastic combined bending and torsion of I-section beams is investigated in this paper using the finite element method. The elastic-plastic load-deformation relationships of beams under combined bending and torsion are determined by taking into account the effects of large deformations, material inelasticity, and initial conditions of residual stresses and geometric imperfections. The interactions between in-plane bending, lateral buckling, and torsion are studied. The effects of secondary bending actions about the minor axis caused by torsional rotations are important for the interaction between bending (with flexural-torsional buckling) and destabilizing torsion. Interaction equations for the design of I-section beams against combined bending and free torsion, and against combined flexural-torsional buckling and destabilizing torsion are proposed. It is found that a commonly quoted circular interaction equation for combined bending and torsion does not always provide a true lower bound for I-section beams. NTIS

INFLUENCE OF PRIMARY BOUNDARY CONDITIONS ON THE BUCKLING OF SHALLOW CYLINDRICAL SHELLS
H. Showkati and P. Ansourian Jan. 1994 62 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(PB94-208352; R-684) Avail: CASI HC A04

Slender cylinders of intermediate length subjected to external pressure normally buckle into sinusoidal waves in the circumferential and meridional directions; the wave numbers are a function of the edge restraints, aspect ratio L/R and wall slenderness R/t. All instability formulas purporting to evaluate the lowest eigenvalue require minimization with respect to the circumferential wave number n; any 'exact' formulation requires the a-priori evaluation of n. Therefore, in any investigation of the effect of boundary conditions on the buckling pressure q(cr) the evaluation of n is crucial. In this paper, a numerical study is presented of the influence of 11 separate sets of boundary conditions on the circumferential wavenumber n and the buckling pressure q(cr). It is found that, as the restraint of the cylinder edged increases, the meridional wavelength decreases, and the wavenumber n increases. It is also found in the investigation that for the higher wavenumbers, the follower load effect on the buckling mode is small. NTIS

A COMPUTATIONAL STUDY OF PROJECTILE SHAPE DEPENDENCE ON PHASE CHANGE PHENOMENA WITH COMPARISONS TO EXPERIMENTAL DATA
E. S. Hertel, Jr., R. L. McIntosh, and B. C. Patterson (Wright Lab., Wright-Patterson AFB, OH.) 1994 8 p Presented at the American Institute of Aeronautics and Astronautics Space Programs and Technologies Conference and Exhibit, Birmingham, AL, 27 Sep. 1994
(Contract DE-AC04-94AL-85000)
(DE95-000740; SAND-94-0060C; CONF-9409211-2) Avail: CASI HC A02/MF A01

To make an estimate of the current state of predictive capabilities of hydrocodes for impacts where phase changes may be important, we have simulated a series of experiments where a zinc sphere, rod, and plate impact thin zinc plates at 5 km/s. The experimental data consists of radiographs of the debris cloud and visual evidence of the damage in an aluminum witness plate. CTH was used to simulate the three experiments noted above. A detailed comparison of the simulated debris structure and subsequent damage will be made with the available data. In general, the CTH predictions match the experimental record. DOE

INELASTIC TORSION OF STEEL I-BEAMS
Y. L. Pi and N. S. Trahair Sep. 1993 44 p See also PB94-104817, PB94-104825 and PB94-208378
(PB94-208360; R-679) Avail: CASI HC A03/MF A01

A nonlinear inelastic analysis of the non-uniform torsion of I-section beams is presented in this paper. Large twist rotations are included in the geometry non-linearity. The nonlinear equilibrium equations of beams in nonuniform torsion have been derived and a finite element procedure has been developed based on the analysis. The elastic-plastic behavior of beams in non-uniform torsion is studied using the finite element procedure and the results are compared with tests. It is found that I-section beams have much larger torsional capacities than can be predicted by linear plastic collapse analysis, and that torsional failure occurs not by the formation of a mechanism but by the tensile rupture of the flanges. A method is proposed for calculating the full plastic non-uniform torque for practical design purposes. NTIS

TURBULENCE DESCRIPTORS FOR SCALING FATIGUE LOADING SPECTRA OF WIND TURBINE STRUCTURAL COMPONENTS
N. D. Kelley Jul. 1994 10 p Presented at the International Energy Agency Meeting on Wind Conditions for Wind Turbine Design, Hamburg, Germany, 27-28 Jun. 1994
(Contract DE-AC36-83CH-10093)
(DE94-011833; NREL/TP-442-7035; CONF-9406223-1) Avail: CASI HC A02/MF A01

The challenge for the designer in developing a new wind turbine is to incorporate sufficient strength in its components to safely achieve a 20- or 30-year service life. To accomplish this, the designer must understand the load and stress distributions (in a statistical sense at least) that the turbine is likely to encounter during its operating life. Sources of loads found in the normal operating environment include start/stop cycles, emergency shutdowns, the turbulence environment associated with the specific site and turbine location, and extreme or 'rare' events that can challenge the turbine short-term survivability. Extreme events can result from an operational problem (e.g., controller failure) or violent atmospheric phenomena (tornadic circulations, strong gust fronts). For the majority of the operating time, however, the character of the turbulent inflow is the dominant source of the alternating stress distributions experienced by the structural components. Methods of characterizing or scaling the severity of the loading spectra (or the rate of fatigue damage accumulation) must be applicable to a wide range of turbulent inflow environments - from solitary isolation to the complex flows associated with multi-row wind farms. The metrics chosen must be related to the properties of the turbulent inflow and independent of the nature of local terrain features. DOE

APPLICATION OF AN ENERGY-BASED LIFE PREDICTION MODEL TO BITHERMAL AND THERMOMECHANICAL FATIGUE

V. M. Radhakrishnan (Indian Inst. of Tech., Madras.), Sreeramesh Kalluri (NYMA, Inc., Brook Park, OH.), and Gary R. Halford Jul. 1994 18 p
Sponsored by NAS-NRC
(Contract NAS3-27186; RTOP 505-63-5B)
(NASA-TM-106684; E-9038; NAS 1.15:106684) Avail: CASI HC A03/MF A01

The inelastic hysteresis energy applied to the material in a cycle is used as the basis for predicting nonisothermal fatigue life of a wrought cobalt-base superalloy, Haynes 188, from isothermal fatigue data. Damage functions that account for hold-time effects and time-dependent environmental phenomena such as oxidation and hot corrosion are proposed in terms of the inelastic hysteresis energy per cycle. The proposed damage functions are used to predict the bithermal and thermomechanical fatigue lives of Haynes 188 between 316 and 760 C from isothermal fatigue data. Predicted fatigue lives of all but two of the nonisothermal tests are within a factor of 1.5 of the experimentally observed lives. Author

A COMPUTATIONAL STUDY OF PROJECTILE MELT IN IMPACT WITH TYPICAL WHIPPLE SHIELDS

M. L. Alme (Alme and Associates, Columbia, MD.) and C. E. Rhoades, Jr. 3 Jun. 1994 23 p Presented at the 1994 Hypervelocity Impact Symposium, Santa Fe, NM, 16-20 Oct. 1994
(Contract W-7405-eng-48)
(DE94-016454; UCRL-JC-116598; CONF-9410131-4) Avail: CASI HC A03/MF A01

This paper presents scaling results based on simulations with the CALE hydrodynamics code of aluminum projectile impacts on typical aluminum Whipple shields at speeds of 6 to 14 km/s. The objective was to determine the extent of projectile and target material melting. The approach was to perform a matrix of computer simulations varying the impact speed from 6 to 14 km/s and varying the areal density of the shield from 5 percent to 80 percent of the centerline areal density of the projectile. The projectile radius was fixed at 9.5 mm (mass = 1.27 grams). The melt state of the projectile material and the shield material was assessed after release of the initial shock. The post-release specific energy in the projectile and in the shield was compared with the enthalpy of incipient melt and the enthalpy of complete melt provided in the Hultgren Tables. Material with specific energy greater than the enthalpy of complete melt was assumed to be fully melted; material with specific energy greater than the enthalpy of incipient melt but less than that of complete melt was assumed to be partially solid and partially melted mixed phase material with no strength; and material with specific energy less than the enthalpy of incipient melt was assumed to be in a solid state with strength. It is likely that this solid material is in a highly fragmented state as a result of the initial shock. DOE

AN OVERVIEW OF THE HSST FULL-THICKNESS SHALLOW-CRACK CLAD BEAM TESTING PROGRAM

J. A. Keeney, T. J. Theiss, W. J. McAfee, and B. R. Bass 1994 7 p Presented at the 12th Biennial Conference for the International Association for Structural Mechanics in Reactor Technology (SMIRT 12), Stuttgart, Germany, 16-26 Aug. 1993
(Contract DE-AC05-84OR-21400)
(DE94-018940; CONF-930803-32) Avail: CASI HC A02/MF A01

A testing program is described that will utilize full-thickness clad beam specimens to quantify fracture toughness for shallow flaws in material for which metallurgical conditions are prototypic of those found in reactor pressure vessels (RPV's). The beam specimens are fabricated from a section of an RPV wall that includes weld, plate and clad material. Metallurgical factors potentially influencing fracture toughness for shallow flaws in the beam specimen include material gradients due to welding and cladding applications, as well as material inhomogeneities in welded regions due to reheating in multiple weld passes. Fracture toughness tests focusing on shallow flaws in plate and weld material will also provide data for evaluating the relative influence of absolute and normalized crack depth on constraint conditions. Pretest finite-element analyses are described that provide near-tip stress and strain fields for characterization of constraint in the shallow-crack specimens in terms of the Q-stress. Analysis results predict a constraint loss in the shallow-crack clad beam specimen similar to that determined for a previously tested shallow-crack single-edge notch homogeneous bend specimen with the same normalized crack depth. RESIDUAL STRESSES IN MATERIAL PROCESSING

K. J. Kozaczek, T. R. Watkins, C. R. Hubbard, Xun-Li Wang, and S. Spooner 1994 7 p Presented at the 1994 Pressure Vessels and Piping Conference, Minneapolis, MN, 19-23 Jun. 1994
(Contract DE-AC05-84OR-21400)
(DE94-017888; CONF-940613-26) Avail: CASI HC A02/MF A01

Material manufacturing processes often introduce residual stresses into the product. The residual stresses affect the properties of the material and often are detrimental. Therefore, the distribution and magnitude of residual stresses in the final product are usually an important factor in manufacturing process optimization or component life prediction. The present paper briefly discusses the causes of residual stresses. It then addresses the direct, nondestructive methods of residual stress measurement by X ray and neutron diffraction. Examples are presented to demonstrate the importance of residual stress measurement in machining and joining operations. DOE

DYNAMIC MEASUREMENT OF THE HOOP MODULUS OF A COMPOSITE CYLINDER

J. B. Andriulli 1994 11 p Presented at the Annual Winter Meeting of the American Society of Mechanical Engineers, New Orleans, LA, 28 Nov. - 3 Dec. 1993
(Contract DE-AC05-84OR-21400)
(DE94-018958; CONF-931121-39) Avail: CASI HC A03/MF A01

Hoop modulus of a composite cylinder is measured by the impact-hammer modal-test method of a ring-segment specimen suspended in the near free-free boundary condition. The ring segment is cut from one end of the composite cylinder forming a curved bar with curvature equal to the radius of the cylinder. Free-free axial resonances are imposed by striking one end of the curved bar with a hammer. Axial response is measured by a miniature accelerometer on either end of the bar. The axial modulus of the curved bar is determined from the bar material density and the axial resonances in a manner similar to that used to determine modulus from axial resonances of a straight bar. An algorithm is used to correct for the frequency shift of the axial modes due to the bar curvature. The use of higher-axial modes minimizes bar curvature effects on frequency and improves accuracy. The hoop modulus of the composite cylinder is assumed to be the same as that determined from the axial modulus of the curved bar (ring segment). The measurement method has been confirmed by conducting the procedure on straight and curved aluminum bars and ring segments of two different lengths and three different curvatures. The method has been successfully demonstrated with aluminum and composite ring segments having circumferential arc lengths ranging from 60 degrees to 305 degrees. Both measured and computed results are compared and shown to be in good agreement. DOE

THE PRODUCTION OF CALIBRATION SPECIMENS FOR IMPACT TESTING OF SUBSIZE CHARPY SPECIMENS
D. J. Alexander, W. R. Corwin, and T. D. Owings 1994 8 p Presented at the Symposium on Pendulum Impact Machine: Procedures and Specimens for Verification, Montreal, Quebec, 18-19 May 1994
(Contract DE-AC05-84OR-21400)
(DE94-018125; CONF-9405223-1) Avail: CASI HC A02/MF A01

Calibration specimens have been manufactured for checking the performance of a pendulum impact testing machine that has been configured for testing subsize specimens, both half-size (5.0 x 5.0 x 25.4 mm) and third-size (3.33 x 3.33 x 25.4 mm). Specimens were fabricated from quenched-and-tempered 4340 steel heat treated to produce different microstructures that would result in either high or low absorbed energy levels on testing. A large group of both half- and third-size specimens were tested at -40 C. The results of the tests were analyzed for average value and standard deviation, and these values were used to establish calibration limits for the Charpy impact machine when testing subsize specimens. These average values plus or minus two standard deviations were set as the acceptable limits for the average of five tests for calibration of the impact testing machine. DOE

RELIABILITY ANALYSIS OF UNIAXIALLY GROUND BRITTLE MATERIALS
Jonathan A. Salem, Noel N. Nemeth, Lynn M. Powers, and Sung R. Choi Feb. 1995 14 p Presented at the Turbo Expo 1995, Houston, TX, 5-8 Jun. 1995; sponsored by ASME
(Contract RTOP 505-63-5B; DE-AC05-840R-21400)
(NASA-TM-106852; E-9441; NAS 1.15:106852) Avail: CASI HC A03/MF A01

The fast fracture strength distribution of uniaxially ground, alpha silicon carbide was investigated as a function of grinding angle relative to the principal stress direction in flexure. Both as-ground and ground/annealed surfaces were investigated. The resulting flexural strength distributions were used to verify reliability models and predict the strength distribution of larger plate specimens tested in biaxial flexure. Complete fractography was done on the specimens. Failures occurred from agglomerates, machining cracks, or hybrid flaws that consisted of a machining crack located at a processing agglomerate. Annealing eliminated failures due to machining damage. Reliability analyses were performed using two and three parameter Weibull and Batdorf methodologies. The Weibull size effect was demonstrated for machining flaws. Mixed mode reliability models reasonably predicted the strength distributions of uniaxial flexure and biaxial plate specimens. Author

GEOMETRIC MOIRE METHOD OF STRAIN ANALYSIS WITH DISPLACEMENT DISCONTINUITIES
S. R. Brown and R. D. Hardy Aug. 1994 57 p
(Contract DE-AC04-94AL-85000)
(DE95-001114; SAND-93-1157) Avail: CASI HC A04/MF A01

Prediction of the deformation behavior of large engineering structures in jointed rock under a specified loading history requires the extensive use of numerical simulation. For example, the evaluation of the stability of the openings for the Exploratory Studies Facility and a potential repository for high-level nuclear waste at Yucca Mountain, Nevada will require computer codes capable of predicting slip on rock joints resulting from changes in thermal stresses. The testing and ultimate validation of these complex finite element computer codes is an important step in their development before their use as a design tool for an engineering structure or for the study of some other practical problem. While field tests may be ultimately necessary, the authors propose a different and more thorough approach where early tests are done on a bench scale with easily characterized materials and geometries. For these bench-scale tests, the basic approach is to construct a laboratory specimen with a known geometry from an easily characterized material. Digital video imaging combined with the geometric moire fringe method of strain analysis is used to measure and derive the displacements on the sample under load. Here the authors present the method of acquiring and analyzing the moire data and give an analysis of its problems and benefits. DOE

GEOMATERIAL MODELS AND NUMERICAL ANALYSIS OF SOFTENING Ph.D. Thesis
R. B. J. Brinkgreve 24 May 1994 64 p Sponsored by Technology Foundation (STW), Dutch Ministry of Transport, Public Works and Water Management, and Shell Research
(PB95-135380; ISBN-90-9007034-6) Avail: CASI HC A04/MF A01

Since 1960, researchers have been working on constitutive models for geomaterials, i.e. soil and rock. In later years such models have been applied in finite element codes, in particular the simple elastoplastic Mohr-Coulomb model. More refined models exist, but they are not easily applied in practical geotechnical engineering. Even well-known Cam-Clay type models are, as yet, not generally applied for clays, and are subject to criticism. From a practical point of view, the criticism concerns among other things the prediction of lateral stresses in soil layers. From a theoretical point of view, the quite general use of non-conservative elasticity laws is not justified. In fact, a proper potential for the elastic strain-energy is missing. This study is among other things aimed at improving this situation, and some improvements of existing constitutive models are proposed. Another quite different part of this study concerns a new topic of geomechanics, namely non-local material softening. Dense clays and rock show material softening, i.e. negativeness of the second-order work, but classical softening models lead to ill-posed formulations. Numerical calculations with such models produce unreliable results. Recently, some researchers have put forward new ideas for arriving at well-posedness of boundary value problems. Stimulated by some pioneering work in this field, a so-called non-local approach is put into operation. NTIS

ACCURACY PROBLEMS IN THE GENERATION OF DISCRETE TIME STOCHASTIC PROCESSES
Thomas Svensson 1994 26 p
(ISSN 0284-5172)
(PB95-131397; SP-RAPP-1994:24; ISBN-91-7848-483-9) Avail: CASI HC A03/MF A01

A method for the generation of discrete time stochastic processes for fatigue testing was previously presented. The generated process is constructed according to user requirements regarding irregularity and level crossings. In the present investigation this type of discrete time stochastic process is further investigated in order to calculate prediction limits for user requirements. These limits can be used to decide the length of sequences that need to be generated in a certain fatigue test. For instance, our results show that irregularity factor errors better than 1% are possible to achieve in fatigue applications. NTIS

A MODEL OF AN INFINITE LENGTH, AXISYMMETRIC, ISOTROPIC, FORCED THICK SHELL Final Report
Andrew J. Hull 22 Aug. 1994 39 p
(AD-A285586; NUWC-NPT-TR-10719) Avail: CASI HC A03/MF A01

The model described in this report provides an exact solution to the equations of motion for an infinite length, axisymmetric, isotropic, forced thick shell. In this model, the governing equations of motion of an isotropic elastic solid in cylindrical coordinates are first separated into a dilatational wave equation and three distortional wave equations that can be solved with Bessel functions. These general solutions are then inserted into stress-strain constitutive equations at the interior and exterior of the shell. The displacements are next determined from forcing functions that are applied to the shell. In this new model, the shell thickness effects on wave propagation are addressed. The case where the mean radius of the shell is equal to its thickness has been analyzed and compared with thin shell equations of motion. It is shown that, in general, the thin shell equations of motion often underpredict thick shell response. DTIC

TUNGSTEN-URANIUM PENETRATOR TARGET INTERACTION
P. S. Dunn and B. K. Damkroger (Sandia National Labs., Albuquerque, NM.) 1994 14 p Presented at the 1994 International Conference on Tungsten and Refractory Metals, McLean, VA, 17-19 Oct. 1994
(Contracts W-7405-eng-36; DE-AC04-94AL-85000)
(DE95-000847; LA-UR-94-3284; CONF-9410213-1) Avail: CASI HC A03/MF A01

Several studies performed in recent years have been directed at determining the penetration mechanism of long rod kinetic energy penetrators into Rolled Homogeneous Armor (RHA). Much of the work has centered on comparing U-0.75Ti and Tungsten Heavy Alloys (WHA), with the goal being to relate the superior ballistic performance of the uranium materials to a fundamental difference in penetration mechanisms. This has been found to be true, with the dominant mechanisms being adiabatic shear in U-0.75Ti and bulk deformation in WHA. Recent work has sought to achieve improvements in the ballistic performance of the tungsten materials via both mechanical property improvements and alloy modifications designed to bring about adiabatic shear. As an alternative, the authors propose the consideration of materials which utilize mechanisms other than bulk deformation and adiabatic shear to optimize ballistic performance. This paper will present the postmortem analysis of a uranium-20 vol% tungsten composite penetrator fired into RHA at 0 degree obliquity. The analysis shows that the penetration mechanism in this material is bulk heating and extensive co-melting of the target and penetrator at the penetration interface. The results of the analysis will then be compared to a similar analysis made of targets into which U-0.75Ti penetrators had been fired. DOE

STRAIN MEASUREMENT BY DIFFRACTION AT LANSCE
M. A. M. Bourke, J. A. Goldstone, and R. A. Robinson 29 Jul. 1994 7 p Presented at the International Conference on Neutron Scattering, Sendai, Japan, 11-14 Oct. 1994 Submitted for publication
(Contract W-7405-eng-36)
(DE94-018264; LA-UR-94-2736; CONF-9410165-3) Avail: CASI HC A02/MF A01

Residual strains affect the structural integrity of components during both fabrication and service and consequently industrial manufacturers routinely invest considerable effort in their characterization and control. Neutron diffraction has proved to be a unique technique for non-destructive strain measurement within crystalline solids. The technique is achieving recognition but is limited by lack of beam time and compromises involved in using instruments designed for powder diffraction. This paper summarizes its importance, lists the capabilities of the Los Alamos (pulsed) neutron scattering center (LANSCE) and briefly describes a concept for a dedicated instrument. DOE

(DE95-001628; SAND-94-0378C; CONF-9409211-4) Avail: CASI HC A03/MF A01

The Hypervelocity Experimental Research Database (HERD) described in this paper was developed to aid researchers with code validation for impacts that occur at velocities faster than the testable regime. Codes of concern include both hydrocodes and fast-running analytical or semi-empirical models used to predict the impact phenomenology and damage that results to projectiles and targets. There are several well documented experimental programs that can serve as benchmarks for code validation; these are identified and described. Recommendations for further experimentation (a canonical problem) to provide validation data are also discussed. DOE

INFLUENCE OF FATIGUE CRACK CLOSURE ON THE GROWTH RATE OF SURFACE FLAWS Final Report, Sep. 1982 - May 1988
William A. Troha Feb. 1994 239 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AF Proj. 3066)
(AD-A279130; WL-TR-92-2032) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Inconsistent experimental results of fatigue crack closure studies over the past 15 years have caused recent investigators to conclude that the fundamental phenomena controlling the crack driving mechanisms are not understood. A major contributor to this misunderstanding is an inadequate understanding of the complex three-dimensional nature of closure. This is true for two-dimensional thru-the-thickness cracks as well as for three-dimensional part-thru surface cracks. To assess the three-dimensional influences of fatigue crack closure on the growth rate of surface flaws, an experimental investigation was conducted using a rectangular plate of polymethyl methacrylate (PMMA) material loaded in four-point bending. The use of transparent PMMA material and a Newton optical interferometer system with a laser light source provided the capability to simultaneously measure three-dimensional crack opening displacement (COD) profiles and closure loads. PERIMETER-YARDSTICK TECHNIQUE FOR FRACTURE SURFACE FRACTAL ANALYSIS Final Report
Gay Kendall, P. J. Cote, and L. V. Meisel Aug. 1994 15 p
(AD-A286240; ARCCB-TR-94028) Avail: CASI HC A03/MF A01

Local fractal dimensions alpha(chi, epsilon), which are closely related to crowding indices of individual islands and lakes formed by sectioning of fracture surfaces produced in Charpy impact testing of a high-strength and high-toughness steel (ASTM A723) alloy, have been determined by perimeter-yardstick analysis. In this type of analysis, the perimeter of an island or lake on a fracture surface section is measured at several different magnifications, and Richardson's equation is employed to determine the fractal dimension of the island or lake. Perimeter-yardstick analysis, which had not previously been applied to fracture surface analysis, yielded alpha(chi, epsilon) values ranging from 1.17 to 1.40 (mean: 1.28, standard deviation: 0.08) for Charpy fracture islands and lakes in ASTM A723 steel for epsilon-values near 0.00013 cm. The mean alpha(chi, epsilon)-value is consistent with the (global) fractal dimension of 1.25 obtained by slit-island analysis of the same fracture surface sections, a value typical of high-strength steel alloys previously studied. The island-to-island and lake-to-lake variations of the local fractal dimensions reflect real variations analogous to differences in the fractal dimensions of the coastlines of Norway and England. Either the fracture surfaces are fractally inhomogeneous or the range of alpha(chi, epsilon)-values determines limits on the variation of the global multifractal dimensions D(q) and a(q). DTIC

EFFECTS OF CYCLIC STRESS DISTRIBUTION MODELS ON FATIGUE LIFE PREDICTIONS
H. J. Sutherland and P. S. Veers Oct. 1994 7 p Presented at the American Society of Mechanical Engineers (ASME) Energy Sources Technology Conference and Exhibition, Houston, TX, 29 Jan. - 1 Feb. 1995
(Contract DE-AC04-94AL-85000)
(DE95-001619; SAND-94-2334C; CONF-950116-1) Avail: CASI HC A02/MF A01

The fatigue analysis of a wind turbine component typically uses representative samples of cyclic loads to determine lifetime loads. In this paper, several techniques currently in use are compared to one another based on fatigue life analyses. The generalized Weibull fitting technique is used to remove the artificial truncation of large-amplitude cycles that is inherent in relatively short data sets. Using data from the Sandia/DOE 34-m Test Bed, the generalized Weibull file technique is shown to be excellent for matching the body of the distribution of cyclic loads and for extrapolating the tail of the distribution. However, the data also illustrate that the fitting technique is not a substitute for an adequate data base. DOE

COUNTING METHODS FOR THE ANALYSIS OF LOAD TIME HISTORIES
1994 32 p
(PB95-132916; MEMO-SB-80-106-U) Avail: CASI HC A03/MF A01

Signals of a stochastic nature are usually analyzed on their statistical properties (distribution function, moments, etc.). An important tool for the analysis of both deterministic and stochastic signals is the so-called harmonic analysis. These methods, however, will not be discussed in the present document. This memorandum is concentrated on analysis methods which look for the occurrence of specific events in a load-time trace. These events can be for example the exceedance of specific load levels, the occurrence of a load-change of certain magnitude, etc. As the basis of these analysis techniques is to count the number of times the specified events do occur, these methods are usually indicated as 'counting techniques'. ALUMINIUM OXIDE TARGETS AFTER BALLISTIC IMPACT; FRAGMENTATION OF THE CERAMIC AND THE PROJECTILE [ALUMINIUMOXID EFTER BESKJUTNING; FRAGMENTERING AV KERAM OCH PROJEKTIL]
P. O. Olsson Jun. 1994 29 p In SWAHILI
(PB95-133625; FOA-C-20987-2.3) Avail: Issuing Activity (National Technical Information Service (NTIS))

In this report three different alumina targets are studied after ballistic impact with tungsten alloy long rod projectiles. Two of the targets consist of two well confined circular tiles placed on top of each other and the third one in a single less confined quadratic tile. Three projectile velocities have been used: 1,555 m/s, 1,846 m/s and 2,527 m/s. The different crackpatterns formed, the appearance of the projectile fragments and the importance of the confinement for the armor are discussed. This has been done by comparing the experimental results with models given in the literature. NTIS

RESIDUAL STRESS ANALYSIS IN SWAGE AUTOFRETTAGED THICK-WALLED CYLINDERS BY POSITION-SENSITIVE X-RAY DIFFRACTION TECHNIQUES Final Report
S. L. Lee Aug. 1994 21 p Presented at the ASME International Conference on Pressure Vessels and Piping, Denver, CO, 25-29 Jul. 1993 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A286383; ARCCB-TR-94031) Avail: CASI HC A03

Experimental and theoretical investigations were made for swage autofrettaged partially plastic ASTM A723 steel cylinders with an outside diameter (OD) to inside diameter (ID) ratio of 2.75 and 74 percent overstrain. Residual stress radial distribution and angular stress distribution around the bore were analyzed using two position-sensitive x ray diffraction stress analyzers. Theoretical calculation was made by implementing an interactive, iterative Lotus Works spreadsheet residual stress model on an IBM PC. The model was based on the classical solution to the elastic-plastic deformation problem of a symmetric thickwalled cylinder under internal pressure, including reverse yielding effect. Angular stress distribution data at the ID and OD indicated that non-axisymmetric deformation had occurred during yielding of the cylinders. Excellent agreement was obtained between experimental results and theoretical predictions, including the Bauschinger effect near the bore. By comparing experimental data with theoretical calculations for the 74 percent overstrained cylinders, the Bauschinger factor for the A723 steel was determined to be close to 0.5. Residual stress analysis for the entire cylinder is suggested in the future. DTIC

STRUCTURAL PERFORMANCE OF CYLINDRICAL PRESSURE HOUSINGS OF DIFFERENT CERAMIC COMPOSITIONS UNDER EXTERNAL PRESSURE LOADING. PART 3: SINTERED REACTION BONDED SILICON NITRIDE CERAMIC Final Report
R. R. Kurkchubasche, R. P. Johnson, and J. D. Stachiw Jun. 1994 78 p
(NR Proj. SO3-97)
(AD-A285773; NCCOSC/RDT/E-TR-1592-Pt-3) Avail: CASI HC A05/MF A01

Ten 12-inch-OD by 18-inch-long reaction-bonded sintered silicon-nitride cylinders were fabricated, assembled, and pressure tested to determine their suitability for use as external pressure-resistant housings for underwater applications. The material, designated PSX Si3N4, is made by CERCOM, Inc. (Vista, CA) by a proprietary process. The primary advantages of this material are high compressive strength, high elastic modulus, high fracture toughness, and low specific gravity. Pressure test results are presented along with strain gage data and cyclic fatigue life data. Conclusions regarding the suitability of the material for application to pressure housings for underwater applications are presented along with a comparison to WESGO's AL-600 96-percent alumina ceramic, which was chosen as the base of comparison for various advanced materials being evaluated under the same program. Recommendations for design implementation, nondestructive inspection, and further research are made. DTIC

ICE PROCESSING SYSTEM SOFTWARE SUPPORT DOCUMENTATION Final Report
Sylvia Seal, Barbara Bassett, Douglas A. May, and Florence Fetterer 3 May 1994 112 p
(AD-A280030; NRL/MR/7240-94-7510) Avail: CASI HC A06/MF A02

The Ice Processing System is a digital image processing function that performs sea-ice lead statistics analysis functions and ice-motion estimations. The menu-driven process permits the user to utilize Advanced Very High Resolution Radiometer and/ or Operational Line Scan infrared or visible satellite imagery. The lead analysis software utilizes a Hough transform technique to determine lead orientation statistics. The function also provides/displays lead size, lead orientation, and lead spacing information in various forms to the user. Ice-motion vectors are obtained automatically from image pairs using a cross-correlation technique. The resultant motion vectors are then displayed over a screen image. Together, these techniques provide analysts with near-real-time indications of sea-ice conditions over regions of interest. DTIC

AIRBORNE MULTISENSOR POD SYSTEM (AMPS) DATA ACCESS CONCEPT
Jiing-Yih J. Jou and W. D. Meitzler Oct. 1994 13 p
(Contract DE-AC06-76RL-01830)
(DE95-002586; PNL-10197) Avail: CASI HC A03/MF A01

The purpose of this document is to provide the conceptual design for accessing data collected under the Airborne Multisensor Pod System (AMPS) program and for accessing data about that data. The purpose of the AMPS program is to provide multisensor data for data fusion research as it applies to arms control treaty verification, non-proliferation surveillance, and related programs. Secondary objectives include sensor development and technology demonstration. The program was established by the U.S. Department of Energy (DOE), Office of Arms Control and Non-proliferation (DOE/AN) and is integrated into the overall DOE AN-10.1 technology development program. The AMPS program interacts with other technology programs of DOE/NN-20. The AMPS program participants include five DOE laboratories. Four will be responsible for collecting and supplying data to AMPS data researchers: (1) Lawrence Livermore National Laboratory (LLNL); (2) Remote Sensing Laboratory (RSL); (3) Sandia National Laboratories (SNL); (4) Savannah River Technology Center (SRTC). The Pacific Northwest Laboratory (PNL), has been assigned data management responsibility for the program, which is defined as the process of planning, acquiring, organizing, qualifying and disseminating data. Data ranges from single sensor readings, to high resolution images, to video. The potential volume of data to be collected under the AMPS program will require considerable management effort. The AMPS program specifies a distributed approach for the sharing and management of AMPS data. This approach shares the burden of data distribution across the DOE laboratories, which will be responsible for AMPS instruments development and implementation and the data those instruments produce. This approach will also provide the laboratories with direct control over the distribution of the data for which they are responsible. DOE

INVESTIGATION ON THE BACKSCATTERING PROPERTIES OF FINNISH BOREAL FORESTS AT C- AND X-BAND: A SEMI-EMPIRICAL MODELING APPROACH Ph.D. Thesis
Jouni T. Pulliainen May 1994 128 p
(ISSN 0786-8154)
(PB95-127692; ISBN-951-22-2161-6) Avail: CASI HC A07/MF A02

This study is concerned with the empirical research on microwave radar remote sensing of Finnish boreal forests (C- and X-band signatures). The radar response to forest characteristics, such as the stem volume (or forest biomass), was analyzed, and a semi-empirical model describing the microwave interaction with forests as a function of the forest stem volume was developed. The investigations presented are based on the employment of a high-resolution ranging scatterometer called HUTSCAT (Helsinki University of Technology SCATterometer), and additionally, on the use of satellite-borne ERS-1 Synthetic Aperture Radar (SAR) data. SOLID STATE FREQUENCY CONVERSION TECHNOLOGY FOR REMOTE SENSING
S. P. Velsko, M. S. Webb, W. M. Cook, and W. A. Neuman Jul. 1994 12 p Presented at the 1994 Chemical Analysis By Laser Interrogation of Proliferation Effluents (CALIOPE ITR) Interim Technical Review, Livermore, CA, 26-28 Apr. 1994
(Contract W-7405-eng-48)
(DE94-019102; UCRL-JC-118150; CONF-9404162-11) Avail: CASI HC A03/MF A01

Long range remote sensing from airborne or other highly mobile platforms will require high average power tunable radiation from very compact and efficient laser systems. The solid state laser pumped optical parametric oscillator (OPO) has emerged as a leading candidate for such high average power, widely tunable sources. In contrast to laboratory systems, efficiency and simplicity can be the decisive issues which determine the practicality of a particular airborne remote sensing application. The recent advent of diode laser pumped solid state lasers has produced high average power OPO pump sources which are themselves both compact and efficient. However, parametric oscillator technology which can efficiently convert the average powers provided by these pump sources remains to be demonstrated. In addition to the average power requirement, many airborne long range sensing tasks will require a high degree of frequency multiplexing to disentangle data from multiple chemical species. A key advantage in system simplicity can be obtained, for example, if a single OPO can produce easily controlled multispectral output. In this paper the authors address several topics pertaining to the conversion efficiency, power handling, and multispectral capabilities of OPO's which they are currently investigating. In Section 2, single pulse conversion efficiency issues are addressed, while average power effects are treated in Section 3. Section 4 is concerned with multispectral performance of a single OPO. The last section contains a short summary and some concluding remarks. DOE

OVERVIEW OF REMOTE SENSING LASER DEVELOPMENT AND SEMICONDUCTOR LASER TECHNOLOGY
N. W. Carlson, R. Beach, B. Comaskey, M. Emanuel, T. Scharlemann, J. Skidmore, S. Velsko, B. Krupke, and R. Solarz Jul. 1994 19 p Presented at the 1994 Chemical Analysis By Laser Interrogation of Proliferation Effluents (CALIOPE ITR) Interim Technical Review, Livermore, CA, 26-28 Apr. 1994
(Contract W-7405-eng-48)
(DE94-019103; UCRL-JC-118149; CONF-9404162-12) Avail: CASI HC A03/MF A01

There are many new requirements for remote detection in the atmosphere that have been generated by government agencies. The associated field scenarios anticipated for carrying out the measurements, in many cases, are extremely demanding on the existing technology. Moreover, additional innovations in remote-sensing technology will be needed to satisfy requirements for longer measurement ranges, detection of low concentration levels of target species, new laser wavelengths for a growing list of species, and compact/efficient systems for deployment in airborne platforms. Remote-sensing laser transmitter architectures based on diode-pumped, solid-state lasers offer the most promise in terms of meeting these demanding requirements, although in order to realize this promise, the present level of power performance must be extended by one to two orders of magnitude. The LLNL remote sensing laser development program is aimed at developing those necessary solid-state laser systems with performance characteristics that go well beyond the state-of-the-art. This paper will cover: (1) an overview of the remote sensing laser development program, which includes high-average power solid-state lasers, tunable laser/OPO systems, temperature-insensitive nonlinear materials, and new solid-state/semiconductor laser materials; and (2) a review of the technical progress on semiconductor laser technology development. REVIEW OF GIS APPLICATIONS IN HYDROLOGIC MODELING
Bruce A. DeVantier and Arlen D. Feldman May 1993 21 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A279076; HEC-TP-144) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Geographic information systems (GIS) provide a digital representation of watershed characteristics used in hydrologic modeling. This paper summarizes past efforts and current trends in using digital terrain models and GIS to perform hydrologic analyses. Three methods of geographic information storage are discussed: raster or grid, triangulated irregular network, and contour-based line networks. The computational, geographic, and hydrologic aspects of each data-storage method are analyzed. The use of remotely sensed data in GIS and hydrologic modeling is reviewed. Lumped parameter, physics-based, and hybrid approaches to hydrologic modeling are discussed with respect to their geographic data inputs. Finally, several applications areas (e.g., floodplain hydrology and erosion prediction) for GIS hydrology are described. DTIC

EUROPEAN WORKSHOP ON OPTICAL GROUND TRUTH INSTRUMENTATION FOR THE VALIDATION OF SPACE-BORNE OPTICAL REMOTE SENSING DATA OF THE MARINE ENVIRONMENT
Marcel R. Wernand, ed. 1994 66 p Workshop held on 23-25 Nov. 1993
(ISSN 0923-3210)
(PB95-134144; NIOZ-1994-3) Copyright Avail: Issuing Activity (National Technical Information Service (NTIS))

The primary aims of the workshop were: (1) to define specifications for a multi-band ocean colour ground truth instrument; (2) to design a 'low cost', multi-band ocean colour ground truth instrument to be used from ships and other sea-borne or airborne platforms; and (3) to achieve common procedures for (inter) calibration of marine optical instruments; such procedures are indispendsable to maintain the quality of optical measurements over the years and to ensure compatibility of optical measurement data from different sources. In addition, the possible set-up of a European Optical Databank (ODB) was discussed. Since European coastal waters are largely of Case-2 type, the workshop had its main focus on this type of waters. COMMON MAPPING SYSTEM MEDIA STUDY
Jeffrey R. Leger Apr. 1994 38 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract F19628-94-C-0001)
(AD-A279086; MTR-93B0000043; ESC-TR-93-312) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The Common Mapping System (CMS) defines data formats and standard distribution media for the storage, interchange, and retrieval of mapping, charting, geodesy, and imagery (MCG&I) data. A variety of DOD system are expected to adopt the CMS standard, including mission planning, intelligence, and avionics systems. The distribution media types supported by CMS will significantly impact the utility and cost of CMS for these system. This paper presents the results of an investigation into the attributes of candidate distribution media for CMS, describing cost and production time tradeoffs. We conclude that there would be value in adding compact-disk-read-only-memory (CD-ROM) to erasable optical disk (EOD) as supported distribution media to meet the needs of the Air Force Mission Support System (AFMSS). Additional media types may be necessary to support the requirements of other systems. DTIC

DIGITAL MAPPING, CHARTING, AND GEODESY ANALYSIS PROGRAM TECHNICAL REVIEW OF VECTOR SMART MAP (VMAP) LEVEL 1
H. V. Miller, Kevin B. Shaw, and Susan V. Carter 9 Sep. 1994 23 p
(AD-A286294; NRL/MR/7441-94-7537) Avail: CASI HC A03/MF A01

The Naval Research Laboratory's Digital Mapping, Charting, and Geodesy Analysis Program (DMAP), in an effort to ensure that naval requirements are being met, has performed a technical review of the specification for Vector Smart Map (VMap) Level 1, as directed by the Defense Mapping Agency (DMA) via the Oceanographer of the Navy. VMap, a DMA product formatted in vector product format, will eventually provide users with an excellent source of medium-resolution map data in digital form. Considering only the written specifications, DMAP discovered errors that could hinder not only the production of authentic VMap database libraries but also the user comprehension as well. DMAP emphasizes that essential changes should be made before prototype production begins. Minor suggested changes are also given. DTIC

REMOTE-SENSING BASED TECHNIQUE TO ACCOUNT FOR SUB-GRID SCALE VARIABILITY OF LAND SURFACE PROPERTIES
William L. Crosson and Charles A. Laymon (Institute for Global Change Research and Education, Huntsville, AL.) 1995 7 p Presented at the Conference on Hydrology, Annual Meeting, American Meteorological Society, Dallas, TX, 15-20 Jan. 1995
(Contracts NCC8-22; SUB93-216)
(NASA-TM-110501; NAS 1.15:110501) Avail: CASI HC A02/MF A01

A method has been presented for the representation of sub-grid scale variability of surface properties within a land surface processes model. The method uses remotely-sensed data to directly or indirectly estimate probability density functions (PDF's) or key surface variables. Application of this technique in a coupled land surface-atmosphere model requires only grid-scale values of the variables of interest, obtained from low-resolution satellite imagery or surface/remote sensing data assimilation. The PDF's of each controlling surface property are superimposed on the respective grid-scale values to simulate sub-grid scale heterogeneity. Sensitivity studies will be carried out to ascertain the relative importance of the heterogeneity of several variables, and the degree to which non-linear property-process interactions impact large-scale fluxes. REGIONAL SCALE HYDROLOGY WITH A NEW LAND SURFACE PROCESSES MODEL
Charles Laymon and William Crosson (Institute for Global Change Research and Education, Huntsville, AL.) 1995 7 p Presented at the Conference on Hydrology, Annual Meeting, American Meteorological Society, Dallas, TX, 15-20 Jan. 1995
(Contracts NCC8-22; SUB93-216)
(NASA-TM-110500; NAS 1.15:110500) Avail: CASI HC A02/MF A01

Through the CaPE Hydrometeorology Project, we have developed an understanding of some of the unique data quality issues involved in assimilating data of disparate types for regional-scale hydrologic modeling within a GIS framework. Among others, the issues addressed here include the development of adequate validation of the surface water budget, implementation of the STATSGO soil data set, and implementation of a remote sensing-derived landcover data set to account for surface heterogeneity. A model of land surface processes has been developed and used in studies of the sensitivity of surface fluxes and runoff to soil and landcover characterization. Results of these experiments have raised many questions about how to treat the scale-dependence of land surface-atmosphere interactions on spatial and temporal variability. In light of these questions, additional modifications are being considered for the Marshall Land Surface Processes Model. It is anticipated that these techniques can be tested and applied in conjunction with GCIP activities over regional scales. Author

SOLVING THE INVERSE PROBLEM IN TERRAIN MODELING Final Report, Nov. 1993 - Jul. 1994
Joseph K. Wald Oct. 1994 19 p
(DA Proj. 1L1-61618-AH-43)
(AD-A285860; ARL-TR-605) Avail: CASI HC A03/MF A01

In the computer simulation of combat over a specific geographical area, the terrain is typically represented using sets of isolated, measured terrain altitudes. The 'inverse' problem is to construct in closed form a smooth surface function that matches these measured values to within a prescribed tolerance. If such a surface could be defined, then at any point on the simulated battlefield, both the terrain altitude and the slope of the terrain in any direction could be obtained simply by evaluating the surface functions and its derivatives. Such a terrain description would allow all calculations related to terrain, from line-of-sight to troop movement, to be done more simply and at any desired resolution. In this report, we will show how to solve the inverse problem. DTIC

A MULTISPECTRAL SCANNER SURVEY OF THE IDAHO NATIONAL ENGINEERING LABORATORY AND THE HANFORD RESERVATION
S. B. Brewster, Jr., M. E. Howard, and J. E. Shines Sep. 1994 42 p
(Contract DE-AC08-93NV-11265)
(DE95-003922; EGG-11265-1098) Avail: CASI HC A03/MF A01

An airborne multispectral scanner survey of selected sites on the Idaho National Engineering Laboratory and the Hanford Reservation was performed in mid-November 1993. Aerial multispectral scanner and photography data were acquired coincidentally with the Big O experiment at both locations. To illustrate two potential applications, the multispectral scanner data were digitally enhanced to facilitate the detection of soil disturbance and evidence of surface water transport. The main conclusion of this study was that multispectral data acquired under these conditions can be useful for soil disturbance detection. The imagery did not prove as useful, however, for direct indications of surface water transport. It was possible to infer some water transport patterns from dry water beds, but only if surface indications were present. DOE

This report describes the principal results of work performed during the second year of a 3-year program at the Colorado School of Mines (CSM). The work on transparent conducting oxides was carried out primarily by CSM students at NREL and is described in three publications listed in Appendix C. The high-quality ZnO produced from the work was incorporated into a copper indium diselenide cell that exhibited a world-record efficiency of 16.4%. Much of the time was devoted to the improvement of cadmium sulfide films deposited by chemical bath deposition methods and annealed with or without a cadmium chloride treatment. Progress was also made in the electrochemical deposition of cadmium telluride. High-quality films yielding CdS/CdTe/Au cells of greater than 10% efficiency are now being produced on a regular basis. We explored the use of zinc telluride back contacts to form an n-i-p cell structure as previously used by Ametek. We began small-angle x-ray scattering (SAXS) studies to characterize crystal structures, residual stresses, and microstructures of both CdTe and CdS. Large SAXS signals were observed in CdS, most likely because of scattering from gain boundaries. The signals observed to date from CdTe are much weaker, indicating a more homogeneous microstructure. We began to use the ADEPT modeling program, developed at Purdue University, to guide our understanding of the CdS/CdTe cell physics and the improvements that will most likely lead to significantly enhanced efficiencies. ERROR ANALYSIS IN WIND TURBINE FIELD TESTING
B. McNiff (McNiff Light Industries, Carlisle, MA.) and D. Simms Aug. 1994 8 p Presented at the Windpower 1992, Seattle, WA, 19-23 Oct. 1992
(Contract DE-AC36-83CH-10093)
(DE94-011864; NREL/TP-441-7079; CONF-921049-11) Avail: CASI HC A02/MF A01

In wind turbine field testing, one of the most important issues is understanding and accounting for data errors. Extended dynamic testing of wind turbines requires a thorough uncertainty analysis and a regimen of quality assurance steps in order to preserve accuracy. Test objectives need to be identified to determine the accuracy requirements of any data measurement, collection, and analysis process. Frequently, the uncertainty analysis reveals that the major sources of error can be allowed for with careful calibration and signal drift tracking procedures. This paper offers a basis for the discussion and development of a repeatable and accurate process to track errors and account for them in data processing. DOE

ANALYSES OF GROUNDED AND UNGROUNDED PHOTOVOLTAIC POWER SYSTEMS
Ward Bower and John Wiles (New Mexico State Univ., Las Cruces, NM.) 1994 5 p Presented at the 1st World Conference on Photovoltaic Energy Conversion, Waikoloa, HI, 5-9 Dec. 1994
(Contract DE-AC04-94AL-85000)
(DE94-015015; SAND-94-1774C; CONF-941203-5) Avail: CASI HC A01/MF A01

Photovoltaic (PV) modules and photovoltaic balance of systems equipment are designed, manufactured, and marketed internationally. Each country or group of countries has a set of electrical safety codes, either in place or evolving, that guide and regulate the design and installation of PV power systems. A basic difference in these codes is that some require hard (low-resistance) grounding (the United States and Canada) and others opt for an essentially ungrounded system (Europe and Japan). The significant design and safety issues that exist between the two grounding concepts affect the international PV industry's ability to economically and effectively design and market safe, reliable, and durable PV systems in the global market place. This paper will analyze the technical and safety benefits, penalties, and costs of both grounded arid ungrounded PV systems. The existing grounding practice in several typical countries will be addressed. DOE

POLYCRYSTALLINE CuInSe2 AND CdTe SOLAR CELLS
N. G. Dhere (Florida Solar Energy Center, Cape Canaveral, FL.) Aug. 1994 35 p
(Contract DE-AC36-83CH-10093)
(DE94-011875; NREL/TP-451-6637) Avail: CASI HC A03/MF A01

The principal objective is to develop processes for the fabrication of cadmium-telluride, CdTe, and copper-indium-gallium-diselenide, Cu(In(1-x)Ga(x))Se2, polycrystalline thin-film solar cells using techniques that can be scaled-up for economic manufacture on a large scale. The aims are to fabricate CdTe solar cells using Cd and Te layers sputtered from elemental targets; to promote the interdiffusion between Cd/Te layers, CdTe phase formation, and grain growth; to utilize nontoxic selenization so as to avoid the use of extremely toxic H2Se in the fabrication of Cu(In(1-x)Ga(x))Se2 thin-film solar cells; to optimize selenization parameters; to improve adhesion; to minimize residual stresses; and to improve the uniformity, stoichiometry, and morphology of CdTe and Cu(In(1-x)Ga(x))Se2 thin films, and the efficiency of CdTe and Cu(In(1-x)Ga(x))Se2 solar cells. EXPLORATORY TECHNOLOGY RESEARCH PROGRAM FOR ELECTROCHEMICAL ENERGY STORAGE Executive Summary Report, 1993
Kim Kinoshita, ed. Sep. 1994 13 p
(Contract DE-AC03-76SF-00098)
(DE95-002651; LBL-35566) Avail: CASI HC A03/MF A01

The U.S. Department of Energy's Office of Propulsion Systems provides support for an Electrochemical Energy Storage Program, that includes research and development (R&D) on advanced rechargeable batteries and fuel cells. A major goal of this program is to develop electrochemical power sources suitable for application in electric vehicles (EV's). The program centers on advanced systems that offer the potential for high performance and low life-cycle costs, both of which are necessary to permit significant penetration into commercial markets. The DOE Electrochemical Energy Storage Program is divided into two projects: the Electric Vehicle Advanced Battery Systems (EVABS) Development Program and the Exploratory Technology Research (ETR) Program. The EVABS Program management responsibility has been assigned to Sandia National Laboratories (SNL); Lawrence Berkeley Laboratory (LBL) is responsible for management of the FIR Program. The EVABS and ETR Programs include an integrated matrix of R&D efforts designed to advance progress on selected candidate electrochemical systems. The United States Advanced Battery Consortium (USABC), a tripartite undertaking between DOE, the U.S. automobile manufacturers and the Electric Power Research Institute (EPRI), was formed in 1991 to accelerate the development of advanced batteries for consumer EV's. The role of the FIR Program is to perform supporting research on the advanced battery systems under development by the USABC and EVABS Program, and to evaluate new systems with potentially superior performance, durability and/or cost characteristics. The specific goal of the ETR Program is to identify the most promising electrochemical technologies and transfer them to the USABC, the battery industry and/or the EVABS Program for further development and scale-up. This report summarizes the research, financial and management activities relevant to the ETR Program in CY 1993. DOE

THE PHOTOVOLATIC MANUFACTURING TECHNOLOGY PROJECT (PVMaT) AFTER THREE YEARS
C. Edwin Witt, Richard L. Mitchell, Holly Thomas, and Lloyd O. Herwig (Department of Energy, Washington, DC.) Aug. 1994 6 p Presented at the 29th Intersociety Energy Conversin Engineering Conference, Monterey, CA, 7-12 Aug. 1994
(Contract DE-AC36-83CH-10093)
(DE94-011877; NREL/TP-411-6639; CONF-940812-20) Avail: CASI HC A02/MF A01

The Photovoltaic Manufacturing Technology project (PVMaT) is a government/industry research and development (R&D) partnership involving joint efforts between the federal government (through the US Department of Energy (DOE)) and members of the US photovoltaic (PV) industry. The project's goal is to assist US industry in retaining and extending its world leadership role in the manufacture and commercial development of PV components and systems. PVMaT is being carried out in three separate phases, each designed to address separate R&D requirements for achieving PVMaT goals. Phase 1 was a problem identification phase of about 3 months duration. In Phase 1, the status and needs of the US PV manufacturing industry were identified, and the development of a Phase 2 procurement responsive to the industry's needs was begun. Phase 1 was completed in 1991. Problem solution began in 1992, under Phase 2A, when DOE awarded multiyear subcontracts. Technical accomplishments for PVMaT 2A are presented in this paper. Subcontracts were recently awarded for a second, overlapping, and similar process-specific solicitation (PVMaT 2B). The activities of these new subcontracts are also described. Two subcontracts presently comprise the Phase 3 effort. Phase 3 addresses R&D problems that are relatively common to a number of PV companies or the PV industry as a whole. A teamed research approach is being used to improve automated module manufacturing lines and encapsulation materials used in module manufacturing. The first year's work on these subcontracts is also described in this paper. DOE

MULTIPLY MANIFOLDED MOLTEN CARBONATE FUEL CELLS
M. Krumpelt, M. F. Roche, H. K. Geyer, and S. A. Johnson 1994 4 p Presented at the Fuel Cells 1994, Morgantown, WV, 17-19 Aug. 1994
(Contract W-31-109-eng-38)
(DE94-017074; ANL/CMT/CP-83649; CONF-940883-1) Avail: CASI HC A01/MF A01

This study consists of research and development activities related to the concept of a molten carbonate fuel cell (MCFC) with multiple manifolds. The objective is to develop an MCFC having a higher power density and a longer life than other MCFC designs. The higher power density will result from thinner gas flow channels; the extended life will result from reduced temperature gradients. Simplification of the gas flow channels and current collectors may also significantly reduce cost for the multiply manifolded MCFC. DOE

ACCELERATORS FOR ENERGY PRODUCTION
Takeshi Katayama Nov. 1993 7 p
(DE94-770764; INS-1015) Avail: CASI HC A02/MF A01

A tremendous progress of accelerators for these several decades, has been motivated mainly by the research on subnuclear physics. The culmination in high energy accelerators might be SSC, 20 TeV collider in USA, probably the ultimate accelerator being built with the conventional principle. The technology cultivated and integrated for the accelerator development, can now stably offer the high power beam which could be used for the energy problems. The Inertial Confinement Fusion (ICF) with high current, 10 kA and short pulse, 20 ns heavy ion beam (HIB) of mass number approximately 200, would be the most promising application of accelerators for energy production. In this scenario, the fuel containing D-T mixture, will be compressed to the high temperature, approximately 10 keV and to the high density state, approximately 1000 times the solid density with the pressure of ablative plasma or thermal X ray produced by bombarding of high power HIB. The efficiency, beam power/electric power for accelerator, and the repetition rate of HIB accelerators could be most suitable for the energy production. In the present paper, the outline of HIB ICF (HIF) is presented emphasizing the key issues of high current heavy ion accelerator system. DOE

SOLAR RADIATION RESOURCE ASSESSMENT PROJECT
Jun. 1994 16 p
(Contract DE-AC36-83CH-10093)
(DE94-000286; NREL/SP-463-6156) Avail: CASI HC A03/MF A01

The mission of the Solar Radiation Resource Assessment Project is to provide essential information about the solar radiation resource to users and planners of solar technologies so that they can make informed and timely decisions concerning applications of those technologies. The project team accomplishes this by producing and disseminating relevant and reliable information about solar radiation. Topics include: variability of solar radiation, measurements of solar radiation, spectral distribution of solar radiation, and assessment of the solar resource. FY 1993 accomplishments are detailed. DOE

RECENT REFLUX RECEIVER DEVELOPMENTS UNDER THE US DOE PROGRAM
C. E. Andraka, R. B. Diver, J. B. Moreno, T. A. Moss, and D. R. Adkins 1994 11 p Presented at the 7th International Symposium on Solar Thermal Concentrating Technologies, Moscow, Russia, 26-30 Sep. 1994
(Contract DE-AC04-94AL-85000)
(DE95-001622; SAND-94-1758C; CONF-940970-3) Avail: CASI HC A03/MF A01

The United States Department of Energy (DOE) Solar Thermal Program, through Sandia National Laboratories (SNL), is cooperating with industry to commercialize dish-Stirling technology. Sandia and the DOE have actively encouraged the use of liquid metal reflux receivers in these systems to improve efficiency and lower the levelized cost of electricity. The reflux receiver uses two-phase heat transfer as a 'thermal transformer' to transfer heat from a parabolic tracking-concentrator to the heater heads of the Stirling engine. The two-phase system leads to a higher available input temperature, lower thermal stresses, longer life, and independent design of the absorber and engine sections. Two embodiments of reflux receivers have been investigated: Pool boilers and heat pipes. Several pool-boiler reflux receivers have been successfully demonstrated on sun at up to 64 kWt throughput at SNL. In addition, a bench-scale device was operated for 7500 hours to investigate materials compatibility and boiling stability. Significant progress has also been made on heat pipe receiver technology. Sintered metal wick heat pipes have been investigated extensively for application to 7.5 kWe and 25 kWe systems. One test article has amassed over 1800 hours of on-sun operation. Another was limit tested at Sandia to 65 kWt throughput. These devices incorporate a nickel-powder thick wick structure with condensate return directly to the wick surface. Circumferential tubular arteries are optionally employed to improve the operating margin. In addition, DOE has begun a development program for advanced wick structures capable of supporting the Utility Scale Joint Venture Program, requiring up to 100 kWt throughput. Promising technologies include a brazed stainless steel powdered metal wick and a stainless steel metal felt wick. Bench-scale testing has been encouraging, and on-sun testing is expected this fall. Prototype gas-fired hybrid solar receivers have also been demonstrated. DOE

AN OVERVIEW: COMPONENT DEVELOPMENT FOR SOLAR THERMAL SYSTEMS
T. R. Mancini 1994 14 p Presented at the 7th International Symposium on Solar Thermal Concentrating Technologies, Moscow, Russia, 26-30 Sep. 1994
(Contract DE-AC04-94AL-85000)
(DE95-001623; SAND-94-2431C; CONF-940970-1) Avail: CASI HC A03/MF A01

In this paper, I review the significant issues and the development of solar concentrators and thermal receivers for central-receiver power plants and dish/engine systems. Due to the breadth of the topic area, I have arbitrarily narrowed the content of this paper by choosing not to discuss line-focus (trough) systems and energy storage. I will focus my discussion on the development of heliostats, dishes, and receivers since the 1970s with an emphasis on describing the technologies and their evolution, identifying some key observations and lessons learned, and suggesting what the future in component development may be. DOE

HIGHLIGHTS OF RECENT BALANCE OF SYSTEM RESEARCH AND EVALUATION
M. G. Thomas and J. W. Stevens 1994 7 p Presented at the Photovoltaic Performance and Reliability Workshop, Lakewood, CO, 21-23 Sep. 1994
(Contract DE-AC04-94AL-85000)
(DE95-001626; SAND-94-2498C; CONF-9409170-1) Avail: CASI HC A02/MF A01

The cost of most photovoltaic (PV) systems is more a function of the balance of system (BOS) components than the collectors. The exception to this rule is the grid-tied system whose cost is related more directly to the collectors, and secondarily to the inverter/controls. In fact, recent procurements throughout the country document that collector costs for roof-mounted, utility-tied systems (Russell, PV Systems Workshop, 7/94) represent 60% to 70% of the system cost. This contrasts with the current market for packaged stand-alone all PV or PV-hybrid systems where collectors represent only 25% to 35% of the total. Not only are the BOS components the cost drivers in the current cost-effective PV system market place, they are also the least reliable components. This paper discusses the impact that BOS issues have on component performance, system performance, and system cost and reliability. We will also look at recent recommended changes in system design based upon performance evaluations of fielded PV systems. DOE

TESTING OF THE SAIC FACETS ON THE STRETCHED-MEMBRANE DISH
J. W. Grossman, W. W. Erdman, R. M. Houser, and R. Davenport (Science Applications International Corp., Golden, CO.) Apr. 1994 14 p Presented at the 1995 American Society of Mechanical Engineers/Japanese Society of Mechanical Engineers/Japan Solar Energy Society (ASME/JSME/JSES) International Solar Energy Conference, Maui, HI, 19-24 Mar. 1994
(Contract DE-AC04-94AL-85000)
(DE95-001831; SAND-94-1245C; CONF-9403170-1) Avail: CASI HC A03/MF A01

A dish structure sized for a 25 kW electric dish/generator system has been installed at the National Solar Thermal Test Facility (NSTTF). The dish is used as an optical test bed for prototype stretched-membrane facets. Sandia procured twelve (12) stretched-membrane facets from Science Applications International Corporation (SAIC) for installation on the dish structure. Individual facet optical performance was measured using the 2f test method under development at Sandia. Four facets were tested on-sun using the test truss at the NSTTF prior to installation on the dish structure. During the final stages of the structure assembly, the facets were installed for testing. A distant light source alignment technique was used to align the facets to a 9 meter focal length. The alignment and focus were optimized with on-sun measurements of individual facet characteristics. On-sun flux maps of the image were made using the Beam Characterization System. Calorimetry tests were performed using a cold water calorimeter. This data was used to create a power intercept curve and predict the power inside apertures of different sizes. The focal plane was moved to 9.95 meters and the alignment, optimization, and on-sun tests repeated. This paper presents the results of the testing on the individual facets as well as the results of testing the dish system. The effects of the change in focal length on the optical performance of the dish are shown in the results. DOE

SI CONCENTRATOR SOLAR CELL DEVELOPMENT
D. D. Krut (Spectrolab, Inc., Sylmar, CA.) Oct. 1994 24 p
(Contract DE-AC04-94AL-85000)
(DE95-002314; SAND-94-2453) Avail: CASI HC A03/MF A01

This is the final report of a program to develop a commercial, high-efficiency, low-cost concentrator solar cell compatible with Spectrolab's existing manufacturing infrastructure for space solar cells. The period covered is between 1991 and 1993. The program was funded through Sandia National Laboratories through the DOE concentrator initiative and, was also cost shared by Spectrolab. As a result of this program, Spectrolab implemented solar cells achieving an efficiency of over 19% at 200 to 300X concentration. The cells are compatible with DOE guidelines for a cell price necessary to achieve a cost of electricity of 12 cents a kilowatthour. DOE

DEVELOPMENT OF CONCENTRATOR SOLAR CELLS
Aug. 1994 40 p Prepared for Sandia National Labs., Albuquerque, NM
(Contracts DE-AC04-94AL-85000)
(DE95-002316; SAND-94-2068) Avail: CASI HC A03/MF A01

A limited pilot production run on PESC silicon solar cells for use at high concentrations (200 to 400 suns) is summarized. The front contact design of the cells was modified for operation without prismatic covers. The original objective of the contract was to systematically complete a process consolidation phase, in which all of the process improvements developed during the contract would be combined in a pilot production run. This pilot run was going to provide a basis for estimating cell costs when produced at high throughput. Because of DOE funding limitations, the Photovoltaic Concentrator Initiative is on hold, and Applied Solar's contract was operated at a low level of effort for most of 1993. The results obtained from the reduced scope pilot run showed the effects of discontinuous process optimization and characterization. However, the run provided valuable insight into the technical areas that can be optimized to achieve the original goals of the contract. DOE

PERFORMANCE AND COST ANALYSIS OF MONOLITHIC SOLID OXIDE FUEL CELLS
Mar. 1994 42 p
(Contract DE-AC21-89MC-26006)
(DE95-002511; DOE/MC-26006/3804) Avail: CASI HC A03/MF A01

This report was prepared by AlliedSignal Aerospace Systems & Equipment (ASE) in partial fulfillment of the statement of work (SOW) for Contract DE-AC21-89MC-26006, specifically, item 3, 'Task 5 - Topical Report' of Section C, 'Deliverables.' It comprises an evaluation and optimization of a 2-Mwe monolithic solid oxide fuel (MSOFC) system operating on natural gas fuel, and an update of the stack manufacturing costs developed under Contract DE-AC21-88MC-25166. The system studies are supported by the stack performance model FCELL developed under 'Task 5.1 - Stack Performance Studies.' The system studies show a clear advantage of stacks that are sealed vs. the current 'seal-less' approaches; the sealed stacks achieve extraordinarily high system efficiencies. A market survey supplemented by key inputs from DOE/METC and EPRI personnel led to the power level and fuel selections. DOE

ADVANCED WIND TURBINE DESIGN STUDIES: ADVANCED CONCEPTUAL STUDY
P. Hughes and R. Sherwin Aug. 1994 246 p Prepared in cooperation with Atlantic Orient Corp., Norwich, VT
(Contract DE-AC36-83CH-10093)
(DE93-000031; NREL/TP-442-4740) Avail: CASI HC A11/MF A03

In conjunction with the US Department of Energy and the National Renewable Energy Laboratory's Advanced Wind Turbine Program, the Atlantic Orient Corporation developed preliminary designs for the next generation of wind turbines. These 50 kW and 350 kW turbines are based upon the concept of simplicity. By adhering to a design philosophy that emphasizes simplicity, we project that these turbines will produce energy at extremely competitive rates which will unlock the potential of wind energy domestically and internationally. The program consisted of three distinct phases. First, we evaluated the operational history of the Enertech 44 series wind turbines. As a result of this evaluation, we developed, in the second phase, a preliminary design for a new 50 kW turbine for the near-term market. In the third phase, we took a clean-sheet-of-paper approach to designing a 350 kW turbine focused on the mid-1990s utility market that incorporated past experience and advanced technology. DOE

PROCESSING AND MODELING ISSUES FOR THIN-FILM SOLAR CELL DEVICES
R. W. Birkmire, J. E. Phillips, W. A. Buchanan, S. S. Hegedus, B. E. McCandless, W. N. Shafarman, and T. A. Yokimcus Sep. 1994 206 p Prepared for National Renewable Energy Lab., Golden, CO
(Contract DE-AC36-83CH-10093)
(DE94-011895; NREL/TP-451-7056) Avail: CASI HC A10/MF A03

The overall objective of the research presented in this report is to advance the development and acceptance of thin-film photovoltaic modules by increasing the understanding of film growth and processing and its relationship to materials properties and solar cell performance. The specific means toward meeting this larger goal include: (1) investigating scalable, cost-effective deposition processes; (2) preparing thin-film materials and device layers and completed cell structures; (3) performing detailed material and device analysis; and (4) participating in collaborative research efforts that address the needs of PV-manufacturers. These objectives are being pursued with CuInSe2, CdTe, and a-Si based solar cells. DOE

SOLID OXIDE FUEL CELLS IN THE UNITED STATES
Diane Traub Hooie 1994 11 p Presented at the 1st European Solid Oxide Fuel Cell Forum: Engineering, Systems, Applications, Lucerne, Switzerland, 3-7 Oct. 1994
(DE95-002405; DOE/METC-C/95/7162; CONF-9410170-1) Avail: CASI HC A03/MF A01

This paper presents an overview of the solid-oxide fuel cell program being undertaken in the US. This program addresses both intermediate and high temperature fuel cells as well as a variety of configurations including planar/monolithic, and tubular. These projects also address a variety of issues such as material compatibility, life/degradation, fuel compatibility, and system scaleup and integration. The primary applications currently being developed is for power generation but a variety of other potential applications, such as transportation, are being considered. The funding for these projects is provided through a variety of sources including the US Government (primarily Departments of Energy, Transportation, and Defense), the Electric Power Research Institute (EPRI), the Gas Research Institute (GRI), and industry. (Contract DE-FG05-80CS-83014)
(DE94-015641; DOE/CS-83014/1) Avail: CASI HC A04/MF A01

In August 1980, the US Department of Energy awarded the proposed grant to Georgetown University. The grant covered the following tasks: Task 1, The Department of Energy would participate in the building of an academic facility that would facilitate the integration of flat plate photovoltaic roof modules with an optimally oriented solar architecture. The completion of the facility to be built on the Georgetown University Campus and known as the Georgetown University Intercultural Center was to be a jointly funded endeavor with the Department of Education funding $9.2M through a grant and a loan, Department of Energy funding a maximum of $4M and Georgetown University funding the residual costs. Task 2, Georgetown University would provide the necessary skills, services, materials, equipment and facilities to design, furnish, install and make operational the Georgetown University Intercultural Center Photovoltaic System. The specific objective of this effort would be to build an exemplar flat plate electrical grid connected photovoltaic (PV) system which would demonstrate integration of PV modules into a watertight roofing surface. The system capability, measured at the input to the inverter, would be a 300 kilowatt peak power system as measured at the normal cell operating temperature and an isolation of 100 milliwatts per square centimeter at the collector surface. DOE funding under the grant for the PV system would be limited to a system cost of $20.00 per peak watt up to maximum of six million dollars. DOE

THIN-FILM CADMIUM TELLURIDE PHOTOVOLTAIC CELLS
A. D. Compaan and R. G. Bohn Sep. 1994 32 p Prepared for National Renewable Energy Lab., Golden, CO
(Contract DE-AC36-83CH-10093)
(DE94-011886; NREL/TP-451-7162) Avail: CASI HC A03/MF A01

This report describes work to develop and optimize radio-frequency (RF) sputtering for the deposition of thin films of cadmium telluride (CdTe) and related semiconductors for thin-film solar cells. Pulsed laser physical vapor deposition was also used for exploratory work on these materials, especially where alloying or doping are involved, and for the deposition of cadmium chloride layers. The sputtering work utilized a 2-in diameter planar magnetron sputter gun. The film growth rate by RF sputtering was studied as a function of substrate temperature, gas pressure, and RF power. Complete solar cells were fabricated on tin-oxide-coated soda-lime glass substrates. Currently, work is being done to improve the open-circuit voltage by varying the CdTe-based absorber layer, and to improve the short-circuit current by modifying the CdS window layer. DOE

POWER SYSTEMS FOR FUTURE MISSIONS. APPENDICES A-L Final Report
S. P. Gill, P. E. Frye, Franklin D. Littman, and C. J. Meisl Cleveland, OH NASA Dec. 1994 477 p Prepared for Sverdrup Technologies, Inc., Brook Park, OH
(Contract NAS3-25266)
(NASA-CR-195320-App-A-L; NAS 1.26:195320-App-A-L) Avail: CASI HC A21/MF A04

Selection of power system technology for space applications is typically based on mass, readiness of a particular technology to meet specific mission requirements, and life cycle costs (LCC). The LCC is typically used as a discriminator between competing technologies for a single mission application. All other future applications for a given technology are usually ignored. As a result, development cost of a technology becomes a dominant factor in the LCC comparison. Therefore, it is common for technologies such as DIPS and LMR-CBC to be potentially applicable to a wide range of missions and still lose out in the initial LCC comparison due to high development costs. This collection of appendices (A through L) contains the following power systems technology plans: CBC DIPS Technology Roadmap; PEM PFC Technology Roadmap; NAS Battery Technology Roadmap; PV/RFC Power System Technology Roadmap; PV/NAS Battery Technology Roadmap; Thermionic Reactor Power System Technology Roadmap; SP-100 Power System Technology Roadmap; Dynamic SP-100 Power System Technology Roadmap; Near-Term Solar Dynamic Power System Technology Roadmap; Advanced Solar Dynamic Power System Technology Roadmap; Advanced Stirling Cycle Dynamic Isotope Power System Technology Roadmap; and the ESPPRS (Evolutionary Space Power and Propulsion Requirements System) User's Guide. A PROPOSED WIND MEASUREMENT AND ANALYSIS APPROACH FOR EVALUATING A PROSPECTIVE WIND PLANT SITE
L. L. Wendell, J. C. Barnard, and V. R. Morris May 1994 7 p Presented at the American Wind Energy Association Annual Conference and Exhibition, Minneapolis, MN, 9-13 May 1994
(Contract DE-AC06-76RL-01830)
(DE94-019187; PNL-SA-24143; CONF-940548-8) Avail: CASI HC A02/MF A01

On the basis of research results, cooperative efforts with wind energy developers, and work with meteorological consultants, Pacific Northwest Laboratory (PNL) has proposed an approach for performing wind measurement assessments for prospective wind plant sites. The primary goal of this approach is to effectively balance comprehensiveness with expense. The approach begins with the acquisition of high-resolution digital terrain data for the site. These data are used in computational and visual analyses to determine the best locations for a reference tower and several satellite towers used for wind measurements. The reference tower has wind sensors at three levels: 20, 30, and 40 m. The satellite towers have one sensor at 30 m. The sensors measure the vertical wind speed as well as the horizontal speed and direction. The sampling rate must be at least 4 times per second. The data acquisition system keeps track of turbulence statistics that are saved at intervals from ten minutes to one hour. Statistics for the 30-m level at the satellite towers, as well as the reference tower, provide the mean and variance of the total speed and covariances of the component speeds. The data base produced by this approach over 1-2 years should be valuable for both routine and in-depth analyses. This approach takes advantage of some recent technological developments. It is not being proposed as a standard at this time, but as a tool to be refined with experience. DOE

NON-H2Se, ULTRA-THIN CuInSe2 DEVICES
A. E. Delahoy (Energy Photovoltaics, Inc., Princeton, NJ.), J. Britt (Energy Photovoltaics, Inc., Princeton, NJ.), F. Faras (Energy Photovoltaics, Inc., Princeton, NJ.), and Z. Kiss (Energy Photovoltaics, Inc., Princeton, NJ.) Sep. 1994 34 p
(Contract DE-AC36-83CH-10093)
(DE94-011894; NREL/TP-413-7165) Avail: CASI HC A03/MF A01

This report describes advances made during Phase 2 (November 10, 1992 - November 9, 1993) of a three-phase, cost-shared subcontract whose ultimate goal is the demonstration of thin film CuInSe2 photovoltaic modules prepared by methods adaptable to safe, high yield, high volume manufacturing. At the end of Phase 1, EPV became one of the first groups to clear the 10% efficiency barrier for CIS cells prepared by non-H2Se selenization. During Phase 2 a total area efficiency of 12.5% was achieved for a 1 cm(exp 2) cell. The key achievement of Phase 2 was the production of square foot CIS modules without the use of H2Se. This is seen as a crucial step towards the commercialization of CIS. Using a novel interconnect technology, EPV delivered an 8.0% aperture area efficiency mini-module and a 6.2% aperture area efficiency 720 cm(exp 2) module to NREL. On the processing side, advances were made in precursor formation and the selenization profile, both of which contributed to higher quality CIS. The higher band gap quaternary chalcopyrite material CuIn(S(x)), Se(1-x)2 was prepared and 8% cells were fabricated using this material. Device analysis revealed a correlation between long wavelength quantum efficiency and the CIS Cu/In ratio. Temperature dependent studies highlighted the need for high V(sub OC) devices to minimize the impact of the voltage drop at operating temperature. Numerical modeling of module performance was performed in order to identify the correct ZnO sheet resistance for modules. Efforts in Phase 3 will focus on increase of module efficiency to 9-10%, initiation of an outdoor testing program, preparation of completely uniform CIS plates using second generation selenization equipment, and exploration of alternative precursors for CIS formation. SEAWATER TEST RESULTS OF OPEN-CYCLE OCEAN THERMAL ENERGY CONVERSION (OC-OTEC) COMPONENTS

F. Zangrando (National Renewable Energy Lab., Golden, CO.), D. Bharathan (National Renewable Energy Lab., Golden, CO.), H. Link (National Renewable Energy Lab., Golden, CO.), and C. B. Panchal 1994 23 p
(Contract W-31-109-eng-38)
(DE94-019254; ANL/ES/PP-73762) Avail: CASI HC A03/MF A01

Key components of open-cycle ocean thermal energy conversion systems- the flash evaporator, mist eliminator, passive predeaerator, two surface condenser stages, and two direct-contact condenser stages- have been tested using seawater. These components operate at lower steam pressures and higher inlet noncondensable gas concentrations than do conventional power plant heat exchangers. The rate of heat exchanged between the evaporator and the condenser is on the order of 1.25MW-thermal, requiring a warm seawater flow of about 0.1 cu m/s; the cold seawater flow is on the order of half the warm water flow. In addition to characterizing the performance of the various components, the system has produced potable water from condensation of the steam produced in the evaporator. The information obtained in these tests is being used to design a larger scale experiment in which net power production is expected to be demonstrate for the first time using OC-OTEC technology. DOE

MARS POWER SYSTEM CONCEPT DEFINITION STUDY. VOLUME 1: STUDY RESULTS Final Report

Franklin D. Littman Dec. 1994 100 p
(Contract NAS3-25808; RTOP 326-84-00)
(NASA-CR-195420-Vol-1; E-9361-Vol-1; NAS 1.26:195420-Vol-1) Avail: CASI HC A05/MF A02

A preliminary top level study was completed to define power system concepts applicable to Mars surface applications. This effort included definition of power system requirements and selection of power systems with the potential for high commonality. These power systems included dynamic isotope, Proton Exchange Membrane (PEM) regenerative fuel cell, sodium sulfur battery, photovoltaic, and reactor concepts. Design influencing factors were identified. Characterization studies were then done for each concept to determine system performance, size/volume, and mass. Operations studies were done to determine emplacement/deployment maintenance/servicing, and startup/shutdown requirements. Technology development roadmaps were written for each candidate power system (included in Volume 2). Example power system architectures were defined and compared on a mass basis. The dynamic isotope power system and nuclear reactor power system architectures had significantly lower total masses than the photovoltaic system architectures. Integrated development and deployment time phasing plans were completed for an example DIPS and reactor architecture option to determine the development strategies required to meet the mission scenario requirements. ECONOMIC FEASIBILITY ANALYSIS OF DISTRIBUTED ELECTRIC POWER GENERATION BASED UPON THE NATURAL GAS-FIRED FUEL CELL Final Report

Mar. 1994 100 p
(Contract DE-FC21-92MC-29227)
(DE94-012277; DOE/MC-29227/3849) Avail: CASI HC A05/MF A02

The final report provides a summary of results of the Cost of Ownership Model and the circumstances under which a distributed fuel cell is economically viable. The analysis is based on a series of micro computer models estimates of the capital and operations cost of a fuel cell central utility plant configuration. Using a survey of thermal and electrical demand profiles, the study defines a series of energy user classes. The energy user class demand requirements are entered into the central utility plant model to define the required size the fuel cell capacity and all supporting equipment. The central plant model includes provisions that enables the analyst to select optional plant features that are most appropriate to a fuel cell application, and that are cost effective. The model permits the choice of system features that would be suitable for a large condominium complex or a residential institution such as a hotel, boarding school or prison. Other applications are also practical; however, such applications have a higher relative demand for thermal energy, a characteristic that is well-suited to a fuel cell application with its free source of hot water or steam. The analysis combines the capital and operation from the preceding models into a Cost of Ownership Model to compute the plant capital and operating costs as a function of capacity and principal features and compares these estimates to the estimated operating cost of the same central plant configuration without a fuel cell. DOE

INFLUENCE OF WAVELENGTH ON TRANSIENT SHORT-CIRCUIT CURRENT IN POLYCRYSTALLINE SILICON SOLAR CELLS
B. Ba and M. Kane (Universite Cheikh Anta Diop, Dakar, Senegal.) Oct. 1993 10 p
(DE94-629082; IC-93/348) Avail: CASI HC A02/MF A01 (US Sales Only)

The influence of the wavelength of a monochromatic illumination on transient short-circuit current in an n/p polycrystalline silicon part solar cell junction is investigated. A wavelength dependence in the initial part of the current decay is observed in the case of cells with moderate grain boundary effects. This influence is attenuated in polycrystalline cells with strong grain boundary activity. DOE

RESEARCH ON THE POWER GENERATION SYSTEM WITH THERMOELECTRIC CONVERSION ELEMENTS
Mar. 1994 119 p In JAPANESE
(DE95-714804; NEDO-P-9323) Avail: CASI HC A06/MF A02

The semiconductor thermoelectric power generation system was conceptually designed which utilized, as a case study, a high temperature exhaust heat of 2000 kW from 10MW phosphoric acid fuel cells. Technical problems were then raised to put it to practical use. A system in which the thermoelectric power generation was applied to the heat exchanger of high temperature exhaust water was structured, because the high temperature exhaust heat had to be utilized without thermally unbalancing the fuel cell system. Through studying the influence to be given to the power generation performance by the configuration of module with Bi-Te elements, it was indicated that the present element performance generates power of about 100kW, which corresponds to the net power of about 80kW with a deduction of pumping power. Not only is the element performance enhanced, but it is indispensable to evaluate and demonstrate the reliability which is viewed from the thermomechanical point in the module joining and other thermoelectric power generation parts, and from the point of thermal resistance and other power generation performance in the members and pressure-welded parts. It was pointed out that the system experiment is necessary on a small and medium scale. DOE

(Contract DE-AC04-94AL-85000)
(DE95-003808; SAND-93-0992) Avail: CASI HC A03/MF A01

This report describes the work being done within Sandia's renewable energy program. This work touches on four major disciplines. (1) Photovoltaics. The goal of this project is to develop costeffective, reliable energy system technologies for energy supplies worldwide produced by U.S. industry. It encompasses cell research and development, collector development, technology evaluation, systems engineering, domestic and international applications, and design assistance. (2) Solar Thermal. This project endeavors to develop and increase acceptance of solar thermal electric and industrial technologies as cost-competitive candidates for power generation and to promote their commercialization. Its' major activities are with dish/Stirling systems, the Solar Two power tower, design assistance to industry and users, technology development and research activities. (3) Wind. The wind project impacts domestic and international markets with commercially feasible systems for utility-scale and other applications of wind energy. The project conducts applied research in aerodynamics, structural dynamics, fatigue, materials and controls, and engineering systems, and develops cooperative work with industry. (4) Geothermal. This project is developing technology to increase proven geothermal reserves and is assisting industry in expanding geothermal power on-line. Development work is in stemhole drilling, drilling techniques, instrumentation for geothermal wells, acoustic telemetry, and drilling exploratory wells. DOE

THE LARGE AREA PULSED SOLAR SIMULATOR (LAPSS)
R. L. Mueller 15 Jul. 1994 15 p Revised
(Contract NAS7-1260)
(NASA-CR-197339; JPL-Publ-93-22-Rev-A; NAS 1.26:197339) Avail: CASI HC A03/MF A01

The Large Area Pulsed Solar Simulator (LAPSS) has been installed at JPL. It is primarily intended to be used to illuminate and measure the electrical performance of photovoltaic devices. The simulator, originally manufactured by Spectrolab, Sylmar, CA, occupies an area measuring about 3 m wide x 12 m long. The data acquisition and data processing subsystems have been modernized. Tests on the LAPSS performance resulted in better than plus or minus 2 percent uniformity of irradiance at the test plane and better than plus or minus 0.3 percent measurement repeatability after warm-up. Glass absorption filters reduce the ultraviolet light emitted from the xenon flash lamps. This results in a close match to three different standard airmass zero and airmass 1.5 spectral irradiances. The 2-ms light pulse prevents heating of the device under test, resulting in more reliable temperature measurements. Overall, excellent electrical performance measurements have been made of many different types and sizes of photovoltaic devices. Since the original printing of this publication, in 1993, the LAPSS has been operational and new capabilities have been added. This revision includes a new section relating to the installation of a method to measure the I-V curve of a solar cell or array exhibiting a large effective capacitance. Another new section has been added relating to new capabilities for plotting single and multiple I-V curves, and for archiving the I-V data and test parameters. Finally, a section has been added regarding the data acquisition electronics calibration. Author

ACCELERATED LIFE TESTING OF SOLAR ENERGY MATERIALS: CASE STUDY OF SOME SELECTIVE SOLAR ABSORBER COATING MATERIALS FOR DHW SYSTEMS. A REPORT OF TASK 10 SOLAR MATERIALS RESEARCH AND DEVELOPMENT
Bo Carlsson, Michael Koehl (Fraunhofer-Inst. fuer Solare Energiesysteme, Freiburg, Germany.), Ulrich Frei (Solar Energy Lab., Rapperswil, Switzerland.), and Kenneth Moeller Feb. 1994 264 p Sponsored by International Energy Agency Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(PB95-132411) Avail: CASI HC A12

Accelerated life testing offers the possibility to forecast material service life prior to installation. For the development of new components and systems it, thus, opens a possibility for systematic life cost analysis and material selection. The present report documents the results of a joint study aimed at establishing the use and limitations of methods for accelerated life testing applicable to materials used in solar heating and cooling applications. The study was conducted as part of the work in Task 10 'Solar Materials Research and Development' of the International Energy Agency Solar Heating and Cooling Program. The work was organized as a case study in which four commercially-available selective absorber materials were selected for study. These materials are used in single-glazed flat plate solar collectors for domestic hot water production. NTIS

PRODUCING LIQUID FUELS FROM BIOMASS [POLTTONESTETUOTANTO BIOMASSASTA]
Yrjo Solantausta and Steven Gust (Neste Oy, Porvoo, Finland.) 1994 137 p In FINNISH
(DE95-717458; KTM/E-B-185) Avail: CASI HC A07/MF A02

The aim of this survey was to compare, on techno-economic criteria, alternatives of producing liquid fuels from indigenous raw materials in Finland. Another aim was to compare methods under development and prepare a proposal for steering research related to this field. Process concepts were prepared for a number of alternatives, as well as analogous balances and production and investment cost assessments for these balances. Carbon dioxide emissions of the alternatives and the price of CO2 reduction were also studied. All the alternatives for producing liquid fuels from indigenous raw materials are utmost unprofitable. There are great differences between the alternatives. While the production cost of ethanol is 6 to 9 times higher than the market value of the product, the equivalent ratio for substitute fuel oil produced from peat by pyrolysis is 3 to 4. However, it should be borne in mind that the technical uncertainties related to the alternatives are of different magnitude. Production of ethanol from barley is of commercial technology, while biomass pyrolysis is still under development. If the aim is to reach smaller carbon dioxide emissions by using liquid biofuels, the most favorable alternative is pyrolysis oil produced from wood. Fuels produced from cultivated biomass are more expensive ways of reducing CO2 emissions. Their potential of reducing CO2 emissions in Finland is insignificant. Integration of liquid fuel production to some other production line is more profitable. DOE

Wind energy research has two goals: (1) to gain a fundamental understanding of the interactions between wind and wind turbines; and (2) to develop the basic design tools required to develop advanced technologies. A primary objective of applied research activities is to develop sophisticated computer codes and integrate them into the design, testing, and evaluation of advanced components and systems. Computer models have become a necessary and integral part of developing new high-tech wind energy systems. A computer-based design strategy allows designers to model different configurations and explore new designs before building expensive hardware. DOE works closely with utilities and the wind industry in setting its applied research agenda. As soon as research findings become available, the national laboratories transfer the information to industry through workshops, conferences, and publications. DOE

LABORATORY EVALUATION OF A REACTIVE BAFFLE APPROACH TO NOx CONTROL Final Technical Report, Feb. - Apr. 1993
S. G. Nelson, D. A. VanStone, R. C. Little, and R. A. Peterson Sep. 1993 41 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract F08635-90-C-0053)
(AD-A283802; AL/EQ-TR-1993-0017) Avail: CASI HC A03

Vermiculite, vermiculite coated with magnesia, and activated carbon sorbents have successfully removed NOx (and carbon monoxide and particles) from combustion exhausts in a subscale drone jet engine test cell (JETC), but back pressure so generated elevated the temperature of the JETC and of the engine. The objective of this effort was to explore the feasibility of locating the sorbents in the face of the duct or of baffles parallel to the direction of flow within the ducts. Jet engine test cells (JETC's) are stationary sources of oxides of nitrogen (NOx), soot, and unburned or partially oxidized carbon compounds that form as byproducts of imperfect combustion. Regulation of NOx emissions is being considered for implementation under the Clean Air Act Amendments of 1990. Several principles have been examined as candidate methods to control NOx emissions from JETC's. DTIC

CALCULATION METHODS FOR CRITERIA AIR POLLUTANT EMISSION INVENTORIES Final Report, Feb. 1993 - May 1994
Kurt D. Jagielski and Robert J. OBrien Jul. 1994 90 p
(AD-A284675; AL/OE-TR-1994-0049) Avail: CASI HC A05/MF A01

This report serves as a guidance manual for Bioenvironmental Engineering personnel or other, responsible environmentally-related office in the development of installation-level criteria air pollutant emission inventories. Emission inventories are used to assess and document compliance with federal, state, and local environmental statutes and regulations and can serve as a useful pollution management tool. This report may be used in a stand-alone fashion or in conjunction with an Air Staff-approved emissions software database management program tailored for the Air Force community. Source-specific emissions software, available through the U.S. Environmental Protection Agency for some sources such as motor vehicles and fuel storage tanks, may also be used to assist in calculating and managing emissions data. EFFECTS OF METEOROLOGY ON CONCENTRATIONS OF ACID AEROSOLS
M. P. Zelenka and H. H. Suh (Harvard School of Public Health, Boston, MA.) 1994 8 p
(Contract EPA-CR-816740)
(PB94-209749; EPA/600/A-94/168) Avail: CASI HC A02/MF A01

Ambient air samples of strong acid aerosol, sulfate, ammonia, and ammonium were collected in Pittsburgh and Uniontown, PA during the summer of 1990. High correlations were found for both acid aerosol and sulfate concentrations between Pittsburgh and the semi-rural site in

Uniontown. One possible implication is that acid aerosols and their precursors are regionally transported. To test this hypothesis, air samples from the Uniontown site were statistically analyzed for the meteorological relationships that resulted in episodic events of elevated ambient acid aerosol levels. Standard measures of atmospheric conditions in both Pittsburgh and Uniontown were used; they included temperature, pressure, relative humidity, wind speed and direction. Results show that the episodic events of elevated acid aerosol occurred with the same general set of meteorological conditions. The major meteorological variables which correlated with the episodes were the mean wind speed in Pittsburgh and the mean westerly wind component at Uniontown. These two variables accounted for one-third of the variance. NTIS

DUST BOWL MIGRATION AS AN ANALOG FOR POSSIBLE GLOBAL WARMING-INDUCED MIGRATION FROM MEXICO

M. H. Turner, J. D. Longstreth, A. K. Johnson, and N. J. Rosenberg Jun. 1994 40 p Presented at the 19th Annual Conference and Exposition of the National Association of Environmental Professionals (NAEP): Global Strategies for Environmental Issues, New Orleans, LA, 12-15 Jun. 1994
(Contract DE-AC06-76RL-01830)
(DE94-017472; PNL-SA-23891; CONF-940650-9) Avail: CASI HC A03/MF A01

As a result of increases in CO2 and other radiatively important trace gases, scientists have predicted increases in mean worldwide temperatures of 2 to 5 C over the next 50 to 100 years. Such temperature increases may result in climate modifications that would in turn be associated with increases in drought and desertification and could even change the patterns of the monsoons and tropical rains, which are important to agriculture throughout the world. They predicted that the rise in sea level caused by melting and thermal expansion of glaciers and polar icecaps could flood large population centers, destroying habitation and displacing populations. This will result in approximately 50 million 'environmental refugees' worldwide, triple the number of today. The expected shifts in precipitation are also likely to result in (1) increased runoff contaminated with pesticides, salts, garbage, sewage, and eroded soil, and (2) drought also leading to increased soil erosion and salinization, as well as depletion of limited water resources. The total impact of global warming on agriculture and human habitation could considerably slow the economic development of some nations and would particularly affect agricultural production. Loss of homes, the inability to raise food, an increased prevalence of disease and worsened economic conditions may drive people to leave their homelands, seeking entry into countries which have more resources and greater resistance to the economic consequences of climatic change. This report looks at the possible environmental impacts and economic impacts of the greenhouse effect on Mexico while using the American Dust Bowl event as an analog. DOE

EXPERIMENTAL INVESTIGATION OF PIC FORMATION DURING THE INCINERATION OF RECOVERED CFC-11 Final Report, Jul. 1993 - Jul. 1994

B. Springsteen, L. Ho, and G. Kryder Sep. 1994 238 p
(Contract EPA-68-CO-0094)
(PB94-214772; EPA/600/R-94/163) Avail: CASI HC A11/MF A03

The report gives results of an investigation of the formation of products of incomplete combustion (PIC's) during 'recovered' trichlorofluoromethane (CFC-11) incineration. Tests involved burning the recovered CFC-11 in a propane gas flame. Combustion gas samples were taken and analyzed for volatile organic compounds as well as polychlorinated dibenzo-p-dioxins and dibenzofurans (PCDD/PCDF). Test results confirm that incineration can be used to effectively destroy recovered CFC-11; CFC destruction efficiencies of greater than 99.9999 were consistently demonstrated for CFC-11-to-propane molar ratios of 0.66-0.6. Additionally, low levels were detected when sampling downstream of the flue gas scrubber. Results of a secondary goal of the study, to determine the fate of chlorine (Cl) and fluorine (F), were inconclusive. NTIS

SITE SCIENTIFIC MISSION PLAN FOR THE SOUTHERN GREAT PLAINS CART SITE, JULY - DECEMBER 1994

J. M. Schneider, P. J. Lamb, and D. L. Sisterson (Argonne National Lab., IL.) Jul. 1994 65 p
(Contract W-31-109-eng-38)
(DE94-017289; ARM-94-002) Avail: CASI HC A04/MF A01

The Southern Great Plains (SGP) Cloud and Radiation Testbed (CART) site is designed to help satisfy the data needs of the Atmospheric Radiation Measurement (ARM) Program Science Team. This document defines the scientific priorities for site activities during the six months beginning on July 1, 1994, and also looks forward in lesser detail to subsequent six-month periods. The primary purpose of this Site Scientific Mission Plan is to provide guidance for the development of plans for site operations. It also provides information on current plans to the ARM Functional Teams (Management Team, Experiment Support Team, Operations Team, Data Management Team, Instrument Team, and Campaign Team), and it serves to disseminate the plans more generally within the ARM Program and among the Science Team. This document includes a description of the site's operational status and the primary envisaged site activities, together with information concerning approved and proposed Intensive Observation Periods. Amendments will be prepared and distributed whenever the content changes by more than 30% within a six-month period. The primary users of this document are the site operator, the site scientist, the Science Team through the ARM Program Science Director, the ARM Program Experiment Center, and the aforementioned ARM Program Functional Teams. This plan is a living document that will be updated and reissued every six months as the observational facilities are developed, tested, and augmented and as priorities are adjusted in response to developments in scientific planning and understanding. WORKSHOP ON UNCERTAINTY AND GLOBAL CLIMATE CHANGE RESEARCH

B. E. Tonn and R. Weiher (National Oceanic and Atmospheric Administration, Silver Spring, MD.) Jun. 1994 45 p Workshop held in Knoxville, TN, 22-23 Mar. 1994
(Contract DE-AC05-84OR-21400)
(DE94-016728; ORNL/M-3704-Summ; CONF-9403147-Summ) Avail: CASI HC A03/MF A01

This report summarizes the results and recommendations of the Workshop on Uncertainty and Global Climate Change Research. The purpose of the workshop was to examine in-depth the concept of uncertainty. From an analytical point of view, uncertainty is a central feature of global climate science, economics and decision making. The magnitude and complexity of uncertainty surrounding global climate change has made it quite difficult to answer even the most simple and important of questions: whether potentially costly action is required now to ameliorate adverse consequences of global climate change or whether delay is warranted to gain better information to reduce uncertainties. A major conclusion of the workshop is that multidisciplinary integrated assessments using decision analytic techniques as a foundation is the key to addressing global change policy concerns. First, uncertainty must be dealt with explicitly and rigorously since it is and will continue to be a key feature of analysis and recommendations on policy questions for years to come. Second, key policy questions and variables need to be explicitly identified, prioritized, and their uncertainty characterized to guide the entire scientific, modeling, and policy analysis process. Multidisciplinary integrated assessment techniques and value of information methodologies are best suited for this task. In terms of timeliness and relevance of developing and applying decision analytic techniques, the global change research and policy communities are moving rapidly toward integrated approaches to research design and policy analysis. DOE

AN APPLICATION OF WAVELET TRANSFORM FOR DECOMPOSITION OF MILLIMETER-WAVE SPECTROSCOPIC SIGNALS

K. Gopalan (Purdue Univ., Hammond, IN.), N. Gopalsami, S. Bakhtiari, and A. C. Raptis Aug. 1994 9 p Presented at the 1995 IEEE International Conference on Acoustics, Speech and Signal Processing, Detroit, MI, 8-12 May 1994
(Contract W-31-109-eng-38)
(DE94-018366; ANL/ET/CP-83924; CONF-9405229-1) Avail: CASI HC A02/MF A01

Millimeter-wave technique, based on rotational energy transitions of molecules, holds promise for remote monitoring of environmentally hazardous effluents from processes. Argonne National Laboratory is developing a millimeter-wave sensor based on active swept-frequency radar technique in the frequency range of 220-320 GHz. Because the line widths of millimeter-wave spectra of molecules at atmospheric pressure are broad (approximately 4 GHz half-width at half height), the composite spectrum of multicomponent mixtures of chemicals is generally complex and overlapping. This paper presents an application of discrete wavelet transform for efficient representation and decomposition of millimeter-wave spectral data. A two-layer back propagation neural network is trained using multifrequency wavelet coefficients of the signals as input features and the known composition of different chemicals in the mixture as target output vectors. After training, composition of an unknown mixture of the base chemicals is determined using the wavelet representation of its absorption spectra. Simulated and experimental spectral data were used to test the wavelet transform technique. Accurate values of individual chemical compositions resulted for noise-free laboratory data. In addition, the technique showed more robustness than conventional multivariate techniques under noisy conditions. DOE

INDIRECT GLOBAL WARMING EFFECTS OF OZONE AND STRATOSPHERIC WATER VAPOR INDUCED BY SURFACE METHANE EMISSION

D. J. Wuebbles, A. S. Grossman, J. S. Tamaresis, K. O. Patten, Jr., A. Jain, and K. A. Grant Jul. 1994 38 p
(Contract W-7405-eng-48)
(DE94-019016; UCRL-ID-118061) Avail: CASI HC A03/MF A01

Methane has indirect effects on climate due to chemical interactions as well as direct radiative forcing effects as a greenhouse gas. We have calculated the indirect, time-varying tropospheric radiative forcing and GWP of O3 and stratospheric H2O due to an impulse of CH4. This impulse, applied to the lowest layer of the atmosphere, is the increase of the atmospheric mass of CH4 resulting from a 25 percent steady state increase in the current emissions as a function of latitude. The direct CH4 radiative forcing and GWP are also calculated. The LLNL 2-D radiative-chemistry-transport model is used to evaluate the resulting changes in the O3, H2O and CH4 atmospheric profiles as a function of time. A correlated k-distribution radiative transfer model is used to calculate the radiative forcing at the tropopause of the globally-averaged atmosphere profiles. The O3 indirect GWP's vary from (approximately)27 after a 20 yr integration to (approximately)4 after 500 years, agreeing with the previous estimates to within about 10 percent. The H2O indirect GWP's vary from (approximately)2 after a 20 yr integration to (approximately)0.3 after 500 years, and are in close agreement with other estimates. The CH4 GWP's vary from (approximately)53 at 20 yrs to (approximately)7 at 500 yrs. The 20 year CH4 GWP is (approximately)20% larger than previous estimates of the direct CH4 GWP due to a CH4 response time (approximately)17 yrs that is much longer than the overall lifetime (10 yrs). The increased CH4 response time results from changes in the OH abundances caused by the CH4 impulse. The CH4 radiative forcing results are consistent with IPCC values. Estimates are made of latitude effects in the radiative forcing calculations, and UV effects on the O3 radiative forcing calculations (10%). DOE

RADIATIVE FORCING CALCULATIONS FOR CH3Cl

Allen S. Grossman, Keith E. Grant, and Donald J. Wuebbles Jun. 1994 8 p
(Contract W-7405-eng-48)
(DE94-019018; UCRL-ID-118065) Avail: CASI HC A02/MF A01

Methyl chloride, CH3Cl, is the major natural source of chlorine to the stratosphere. The production of CHCl is dominated by biological sources from the oceans and biomass burning. Production has a seasonal cycle which couples with the short lifetime of tropospheric CH3Cl to produce nonuniform global mixing. As an absorber of infrared radiation, CH3Cl is of interest for its potential affect on the tropospheric energy balance as well as for its chemical interactions. In this study, we estimate the radiative forcing and global warming potential (GWP) of CH3Cl. Our calculations use an infrared radiative transfer model based on the correlated k-distribution algorithm for band absorption. Global and annual average vertical profiles of temperature and trace gas concentration were assumed. The effects of clouds are modeled using three layers of global and annual average cloud optical properties. A radiative forcing value of 0.0053 W/sq m ppbv was obtained for CH3Cl and is approximately linear in the background abundance. This value is about 2 percent of the forcing of CFC-11 and about 300 times the forcing of CO2, on a per molecule basis. The radiative forcing calculation for CH3Cl is used to estimate the global warming potential (GWP) of CH3Cl. The results give GWP's for CH3Cl of the order of 25 at a time of 20 years (CO2 = 1). This result indicates that CH3Cl has the potential to be a major greenhouse gas if significant human related emissions were introduced into the atmosphere. DOE

IMPLEMENTATION AND PERFORMANCE OF A THREE-DIMENSIONAL NUMERICAL TRANSPORT MODEL

B. P. Sommeijer and J. Kok Feb. 1994 35 p
(PB95-135745; CWI-NM-R9402) Copyright Avail: Issuing Activity (National Technical Information Service (NTIS))

We present two numerical solution methods for the time integration of a three-dimensional model for computing transport of salinity, pollutants, suspended material (such as sediment or mud), etc. in shallow seas. The emphasis in this paper is on the performance of the methods when implemented on a vector/parallel, shared memory computer, such as a CRAY type machine. The first method is an explicit time integrator and can straightforwardly be vectorized and parallelized. Although a stabilizing technique has been applied to this method, it still suffers from a severe timestep restriction. The second method is partly implicit, resulting in much better stability characteristics; however, as a consequence of the implicitness, it requires in each step the solution of a large number of tridiagonal systems. When implemented in a standard way, the recursive nature would prevent vectorization, resulting in a very long solution time. Following a suggestion of Golub and Van Loan, this part of the algorithm has been tuned for use on the CRAY Y-MP4/464. On the basis of a large-scale test problem, performance results will be presented for various implementations. NTIS

ENVIRONMENTAL COMPLIANCE ASSESSMENT AND MANAGEMENT PROGRAM Final Report

Carolyn ORourke and Lisa A. Gifford Apr. 1994 243 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A279605; CERL-SR-EC-94/15) Avail: CASI HC A11

The number of environmental laws and regulations has continued to grow in the United States and worldwide, making compliance with these regulations increasingly difficult. Environmental assessments became a way to determine compliance with current environmental regulations. The U.S. Air Force has adopted an environmental compliance program that identifies compliance problems before they are cited as violations by the U.S. Environmental Protection Agency (USEPA). Beginning in 1984, the U.S. Army Construction Engineering Research Laboratories (USACERL), in cooperation with the Air Force Engineering and Services Center, began research on the U.S. Environmental Compliance Assessment and

Management Program (ECAMP). The concept was to combine Federal, Department of Defense (DOD), and Air Force environmental regulations, along with existing checklists from the USEPA and private industry, and documentation of good management practices and risk-management issues, into a series of checklists that list legal requirements and specify items or operations to review. Each assessment protocol lists a point of contact to help assessors review the checklists as effectively as possible. The Hawaii Supplement was developed to be used in conjunction with the U.S. ECAMP manual, using existing Hawaii state environmental legislation and regulations as well as suggested management practices. MONITORING BIOREMEDIATION OF VOLATILE ORGANIC COMPOUNDS (VOCs) USING FOURIER TRANSFORM INFRARED (FT-IR) SPECTROMETRY M.S. Thesis
Vance P. Visser 1994 147 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A279631) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Bioremediation has repeatedly been demonstrated to be an innovative and effective technology for a wide variety of chemically contaminated environments. Although, once predominantly used in wastewater treatment, bioremediation technology is now being applied to soils, ground and surface water, and sludges. The contaminates include chemicals such as crude oil, petroleum hydrocarbons, fuels, and solvents. Regardless of the type of contaminant, the success of any bioremediation approach includes these essential elements; site characterization, initial bioassessment testing, detailed laboratory testing, hydrologic modeling, installation and start-up, process monitoring and operation, final sampling and closure, reporting and management. A major expense in bioremediation can be associated with monitoring the degradation of contaminates. This cost may be reduced by applying readily available, simple analytical methods and instrumentation to the monitoring of the bioremediation process. Our research involves the monitoring of the bioremediation of ground water contaminated by low levels of volatile organic compounds (VOC's) by adapted alfalfa plants and their associated rhizosphere bacteria. ENERGY IMPACTS OF CONTROLLING CARBON DIOXIDE EMISSIONS FROM AN INTEGRATED GASIFICATION/COMBINED-CYCLE SYSTEM
C. D. Livengood, R. D. Doctor, J. C. Molburg, and P. Thimmapuram 1994 10 p Presented at the 10th Annual Coal Preparation, Utilization and Environmental Control Contractors Conference, Pittsburgh, PA, 18-21 Jul. 1994
(Contract W-31-109-eng-38)
(DE94-016878; ANL/ES/CP-83738; CONF-940780-5) Avail: CASI HC A02/MF A01

This paper presents results from a study of the impacts associated with CO2 recovery in integrated gasification/combined-cycle (IGCC) systems which is being conducted for the Morgantown Energy Technology Center by Argonne National Laboratory. The objective of the study is to compare, on a consistent systems-oriented basis, the energy and economic impacts of adding CO2 capture and sequestration to an IGCC system. The research reported here has emphasized commercial technologies for capturing CO2, but ongoing work is also addressing advanced technologies under development and alternate power-system configurations that may enhance system efficiency. ENVIRONMENTAL CLEANUP TECHNOLOGY TRANSFER INITIATIVES Technical Report, Jun. - Jul. 1994
Laurel A. Muehlhausen Aug. 1994 57 p
(AD-A285059; NFESC-TR-2023-ENV) Avail: CASI HC A04/MF A01

This white paper provides brief descriptions of environmental cleanup technology transfer initiatives and points of contact for further information. The summaries describe the mission and goals, the modus operandi or actual activities and projects implemented to achieve the goals, the source and amount of funding for the initiative, and other general information. The initiatives are programs, committees, organizations, and demonstration projects that promote development of innovative environmental cleanup technologies and help ensure the transfer of lower cost technologies into full-scale use. Opinions differ on the meaning of innovative technology. Most of the initiative described here consider a technology innovative if it has been demonstrated at the pilot scale but performance and cost data are lacking. Innovative technologies do not get widely used for many reasons such as risk of failure to meet cleanup standards or unknown cost information. Even if the cleanup succeeds, the project could fail if the public or the regulatory agency distrust a new and different technology. Federal and State agencies, legislatures, and private firms are working to reduce the barriers to technology innovations and commercialization through the initiatives described here. Lower cost technologies are needed to meet environmental cleanup standards in a time of shrinking budgets. Federal lands (military bases, defense production and research facilities, park, forest, and range lands) contain thousands of past disposal sites. The Federal government is committed to the environmental cleanup of these sites although estimates of the cleanup cost exceed $250 billion. Adding in the further cleanup costs of state and private waste sites, the nation's total cleanup estimates exceed $750 billion. DTIC

ENVIRONMENTAL COMPLIANCE ASSESSMENT PROTOCOL - CENTERS FOR DISEASE CONTROL AND PREVENTION (ECAP-CDC), WEST VIRGINIA SUPPLEMENT Final Report
Donald H. Wiggins Nov. 1994 95 p
(AD-A286009; CERL-SR-EC-95/01) Avail: CASI HC A05/MF A01

In response to the growing number of environmental laws and regulations worldwide, the Centers for Disease Control and Prevention (CDC) has adopted an environmental compliance program that identifies compliance problems before they are cited as violations by the U.S. Environmental Protection Agency (USEPA). In 1992, the CDC developed a program to maintain compliance with all Federal, state, and local environmental regulations. The goal is to protect human health/safety and the environment. The CDC, headquarters in Atlanta, Georgia, with facilities in several other states, developed and implemented a specific environmental assessment and management program tailored to the type and size of their facilities and operations. The resulting system combines Federal environmental regulations, along with good management practices and risk management information, into a series of checklists that show legal requirements and which specific items or operations to review. The Environmental Compliance Assessment Protocol Centers for Disease Control and Prevention (ECAP-CDC) incorporates existing checklists from USEPA and private industry. The West Virginia Supplement was developed to be used in conjunction with the ECAP-CDC manual, using existing West Virginia environmental legislation and regulations as well as suggested management practices. CHEMICAL STRUCTURE AND DYNAMICS PROGRAM Annual Report, 1993
S. D. Colson Jul. 1994 58 p

(Contract DE-AC06-76RL-01830)
(DE95-001117; PNL-9445) Avail: CASI HC A04/MF A01

The Chemical Structure and Dynamics program responds to the need for a fundamental, molecular-level understanding of chemistry at the wide variety of environmentally-important interfaces. The research program is built around the established relationship between structure, thermodynamics, and kinetics. This research effort continues to evolve into a program of rigorous studies of fundamental molecular processes in model systems (e.g., well-characterized surfaces, single-component solutions, clusters, and biological molecules), and studies of complex systems found in the environment. Experimental studies of molecular and supramolecular structures and thermodynamics are key to understanding the nature of matter, and lead to direct comparison with computational results. Kinetic and mechanistic measurements, combined with real-time dynamics measurements of atomic and molecular motions during chemical reactions, provide for a molecular-level description of chemical reactions. The anticipated results of this work are the achievement of a quantitative understanding of chemical processes at complex interfaces, the development of new techniques for the detection and measurement of species at such interfaces, and the interpretation and extrapolation of the observations in terms of models of interfacial chemistry. The Chemical Structure and Dynamics research program includes five areas described in detail in this report: Reaction mechanisms at solid interfaces; Solution and solution interfaces; Structure and dynamics of biological systems; Analytical methods development; and atmospheric chemistry. Extended abstracts are presented for 23 studies. DOE

GLOBAL CHANGE INTEGRATING FACTORS: TROPICAL TROPOPAUSE TRENDS
R. A. Reck 1994 10 p
(Contract W-31-109-eng-38)
(DE95-001121; ANL/ER/PP-79069) Avail: CASI HC A02/MF A01

This research proposes new criteria, shifts in the height and temperature of the tropical tropopause, as measures of global climate change. The search for signs of global warming in the temperature signal near the earth's surface is extremely difficult, largely because numerous factors contribute to surface temperature forcing with only a small signal-to-noise ratio relative to long-term effects. In the long term, no part of the atmosphere can be considered individually because the evolution will be a function of all states of all portions. A large surface greenhouse signal might ultimately be expected, but the analysis of surface temperature may not be particularly useful for early detection. What is suggested here is not an analysis of trends in the surface temperature field or any of its spatial averages, but rather an integrating factor or integrator, a single measure of global change that could be considered a test of significant change for the entire global system. Preferably, this global change integrator would vary slowly and would take into account many of the causes of climate change, with a relatively large signal-to-noise ratio. Such an integrator could be monitored, and abrupt or accelerated changes could serve as an early warning signal for policy makers and the public. Earlier work has suggested that temperature has much less short-term and small-scale noise in the lower stratosphere, and thus the global warming signal at that level might be more easily deconvoluted, because the cooling rate near the 200-mb level is almost constant with latitude. A study of the temperature signal at this pressure level might show a clearer trend due to increased levels of greenhouse gases, but it would yield information about the troposphere only by inference. CLOSURE ON THE GLOBAL CARBON CYCLE
Michael R. Riches Aug. 1994 23 p
(DE94-018617; DOE/ER-0620P) Avail: CASI HC A03/MF A01

The Department of Energy's Ocean Margins Program (OMP) is designed to quantitatively assess the importance of coastal ocean systems in the global carbon cycle. Since the beginning of the Industrial Revolution, human energy-related activities have dramatically altered the global carbon cycle, and consequently, this cycle is not presently in a steady-state. To reduce major uncertainties in predicting future global environmental quality, it is imperative to understand the sources and sinks of atmospheric CO2, the role of anthropogenic activities in disrupting the natural carbon cycle, and the effects of, and feedbacks between, these activities and the natural carbon cycle. Due to continuously increased loading of nutrients to the margins, which, globally, is related to the rate of human population growth and high population densities in coastal states, biological carbon fixation has been stimulated. Depending on the fate of the fixed carbon, this stimulation has the potential to mitigate the anthropogenically derived CO2. Determining the factors that control the magnitude of carbon exchanges between the ocean margins and the atmosphere, and the subsequent fate of this carbon, is crucial to predicting the strength and capacity of the oceans to absorb excess anthropogenic atmospheric CO2. The goals of the OMP are to: quantify the ecological and biogeochemical processes and mechanisms that define the cycling, flux, and storage of carbon and other biogenic elements at the land/ocean interface; identify how ocean-margin sources and sinks of carbon change in response to human activities; and determine whether continental shelves are quantitatively significant in removing atmospheric carbon dioxide and isolating it via burial in sediments or export to the interior of the open ocean. EXPLICIT METHODS FOR STIFF ODEs FROM ATMOSPHERIC CHEMISTRY
J. G. Verwer and D. Simpson (Norwegian Meteorological Inst., Blindern, Norway.) Apr. 1994 25 p See also N94-30729 Prepared in cooperation with Norske Meteorologiske Inst., Oslo
(PB95-135794; CWI-NM-R9409) Copyright Avail: Issuing Activity (National Technical Information Service (NTIS))

The subject research is the numerical integration of atmospheric chemical kinetics systems. The application lies in the study of air pollution, modelled by atmospheric chemistry-transport problems. The application puts high demands on the efficiency of the stiff solver. Three explicit methods are discussed and compared for a selected chemical kinetics system which is representative for the state of the art. The first and the second method are of the explicit QSSA type and the third is based on the two-step backward differentiation formula, combined with Gauss-Seidel iteration to approximately solve the implicitly defined solution. This also renders the method explicit. In the comparison the two-step method comes out best. NTIS

ENERGY AND ENVIRONMENTAL ISSUES AND INTERNATIONAL OPPERATION IN ASIA
Mar. 1994 131 p
(DE94-796596; IEE-SR-251) Avail: CASI HC A07/MF A02

Investigation and report were made on the present status of air pollution in major Asian countries except China and their energy and environmental policies. In Asian countries, air pollution has been intensifying because of the progress of industrialization and concentrating population into cities. Pollution, however, is different among countries; SO(x) from the industry in Seoul, suspended particulate matters from transportation in Kuala Lumpur, NO(x) and CO from transportation in Bangkok, SO(x) from power generation and the industry in Jakarta, and soot/smoke in Delhi. Judging from the energy consumption structure, soot/smoke has a connection with coal consumption, SO(x) with coal and petroleum consumption, NO(x) with all fossil fuels. With relation to the environmental legislation and administration system on air pollution, arrangement started in the 1980s, but execution is still poor except for Korea. As for Japan's international cooperation, regarded as important are anti-pollution technology such as desulfurization, thermal efficiency and coal ash treatment, and energy conservation technology. COMPUTER MODEL PREDICTIONS OF THE LOCAL EFFECTS OF LARGE, SOLID-FUEL ROCKET MOTORS ON STRATOSPHERIC OZONE
P. F. Zittel 10 Sep. 1994 23 p
(Contract F04701-93-C-0094)
(AD-A285632; TR-94(4231)-9; SMC-TR-94-36) Avail: CASI HC A03/MF A01

The solid-fuel rocket motors of large space launch vehicles release gases and particles that may significantly affect stratospheric ozone densities along the vehicle's path. In this study, standard rocket nozzle and flowfield computer codes have been used to characterize the exhaust gases and particles through the afterburning region of the solid-fuel motors of the Titan IV launch vehicle. The models predict that a large fraction of the HCl gas exhausted by the motors is converted to Cl and Cl2 in the plume afterburning region. Estimates of the subsequent chemistry suggest that on expansion into the ambient daytime stratosphere, the highly reactive chlorine may significantly deplete ozone in a cylinder around the vehicle track that ranges from 1 to 5 km in diameter over the altitude range of 15 to 40 km. The initial ozone depletion is estimated to occur on a time scale of less than 1 hour. After the initial effects, the dominant chemistry of the problem changes, and new models are needed to follow the further expansion, or closure, of the ozone hole on a longer time scale. DTIC

ATMOSPHERIC STABILITY AND ITS INFLUENCE ON AIR QUALITY IN SMALL COMMUNITIES IN NORTHERN SWEDEN

Per-Erik Johansson, Edward Karlsson, Lennart Thaning, and Bertil Forsberg (Umea Univ., Sweden.) May 1994 78 p
(ISSN 0347-2124)
(PB95-131652; FOA-C-40323-4.5) Avail: CASI HC A05/MF A01

The relation between air quality and meteorology during winter conditions in the northern parts of Sweden has been studied. Several stability schemes has been tested against the measurements and a new improved one has been developed, in order to take into account conditions with low solar altitude, high albedo and low temperatures. At all sites the stratification was stable during more than half of the period. It is shown that the concentration of black smoke may be higher in the studied communities than in much larger cities, under certain conditions. Furthermore it is concluded that the covariance between pollution levels and meteorological parameters are higher in the northern parts of Sweden that in the south. The highest correlation was obtained between black smoke and temperature. NTIS

ICE BABY: MEASUREMENTS OF CONCENTRATION FLUCTUATIONS IN A FOREST AREA IN WINTER CONDITIONS

K. Nyren, D. J. Ride (Chemical and Biological Defense Establishment, Porton Down, England.), and C. D. Jones (Chemical and Biological Defense Establishment, Porton Down, England.) Jun. 1994 63 p
(ISSN 0347-2124)
(PB95-133468; FOA-C-40320-4.5) Avail: CASI HC A04/MF A01

Outdoor experiments to measure atmospheric concentration fluctuations of a tracer gas at high resolution in winter conditions in wooded terrain were conducted in Umea, northern Sweden, in April 1992. The experiments were useful in testing the performance of the new Ultra Violet Ion Collector (UVIC) sensors in a cold climate. The scope of the experiments was limited, but large fluctuations were detected both within the woodland and outside of it. The nature of the fluctuations appeared similar in both locations. Both instantaneous and continuous clouds of tracer gas, propylene, were used. Two UVIC's were employed; both worked well in temperatures around -5 C. Concentration fluctuation statistics from the measured time series are reported. More comprehensive experiments are recommended to assess atmospheric dispersion in winter conditions. The development of an in-field calibration system for the UVIC is proposed. NTIS

EVALUATION OF THE TECHNICAL PERFORMANCE OF THE DUTTCH NATIONAL AIR QUALITY MONITORING NETWORK IN 1992 [EVALUATIE VAN HET FUNCTIONEREN VAN HET LANDELIJK MEETNET LUCHTKWALITEIT IN 1992]

E. Buijsman, D. vanStraalen, P. Swaan, P. W. deVos, and B. G. vanElzakker Jan. 1994 44 p In DUTCH
(PB95-131892; RIVM-723102003) Avail: Issuing Activity (National Technical Information Service (NTIS))

In the report the results of an evaluation of the technical performance of the Dutch National Air Quality Monitoring Network in 1992 are presented. The average brute component efficiencies, i.e. a measure for the availability of measuring data, are: for the automatically measured components (CO, NOx, O3, SO2) 96%; for the meteorological parameters (global radiation, temperature, wind direction, wind speed) 97%; for aerosols etc. (black smoke, acidifying compounds, metals, tsp) 96%; for the chemical composition of precipitation (i.a. acidifying compounds, heavy metals) 96%. Current Dutch legislation requires the measurement of a number of components in such way that only a minimal loss of data is tolerated. The number of stations which did not meet the legal requirements in 1992 are; two for CO (18% of the total number of stations), seven for NO2 (35%), six for SO2 (7%), two for lead aerosol (50%) and 6 for black smoke (30%). OZONE QUALITY CONTROL MEASUREMENTS IN THE DUTCH NATIONAL AIR QUALITY MONITORING NETWORK [KWALITEITSCONTROLEMETINGEN OZON IN HET LANDELIJK MEETNET LUCHTKWALITEIT]

P. Swaan Mar. 1994 25 p In DUTCH
(PB95-131900; RIVM-723101001) Avail: Issuing Activity (National Technical Information Service (NTIS))

From August 1992 until July 1993, ozone quality control measurements were carried out in the Dutch National Air Quality Monitoring Network (LML). Measurement results from 17 LML measurement locations were compared with those from a reference monitor. It can be concluded that on average ozone levels from the LML give an underestimation of 4.9%, which is independent of the absolute measured levels. In some cases, deviations up to 20% are found suggesting the need for further investigation. NTIS

DISINFECTION OF PURIFIED WASTE WATER WITH ULTRA VIOLET LIGHT ON A TECHNICAL SCALE [DESINFECTIE VAN GEZUIVERD AFVALWATER MET ULTRAVIOLET LICHT OP TECHNISCHE SCHAAL]

T. J. Nieuwstad and A. H. Havelaar 1994 95 p In DUTCH Prepared in cooperation with Rijksinstituut voor de Volksgezondheid en Milieuhygiene, Bilthoven, Netherlands Sponsored by Rijksinstituut voor Zuivering van Afvalwater
(PB95-131926) Avail: Issuing Activity (National Technical Information Service (NTIS))

In 1976 the Dutch National Institute for the Purification of Waste Water initiated the project 'The disinfection of sewage plant effluents'. At first the project's supervisory committee concentrated mainly on chemical disinfection. Later it was decided that besides chemical disinfection other methods of disinfection, which do not result in the formation of (harmful) by-products, should be included in the research. On the basis of the experimental studies of the disinfection of purified waste water with ultraviolet light, the Technical University in Delft has carried out further research. This report presents the results of this research. NTIS

DEFINITION REPORT ON ENVIRONMENTAL INDICES IN FUTURE ENVIRONMENTAL ASSESSMENTS ENVIRONMENTAL BALANCE/ENVIRONMENTAL OUTLOOK [DEFINITIERAPPORT GRAADMETERS ATMOSFEER IN DE MILIEUBALANS/MILIEUVERKENNING]

H. Noordijk, H. S. M. A. Diederen, H. vanderWoerd, and K. vanVelze May 1994 99 p In DUTCH
(PB95-131876; RIVM-723308001) Avail: Issuing Activity (National Technical Information Service (NTIS))

The report includes environmental indices that will be an important tool in future environmental assessments (Milieubalansen en Milieuverkenningen). The report defines the indices for the atmosphere. It describes the state of definition at the start of the year 1994, and it is the result of the project group in the Laboratory of Air Research (LLO) of RIVM, with support of some experts within and outside of RIVM. This definition needs to be discussed by all the parties involved with environmental assessments, in order to improve the definition and to obtain consensus on it. The report serves as a basis for these discussions. The indices are clustered in human exposure, ecosystem exposure, depletion of stratospheric ozone, climatic change, decreasing self-cleaning capability of the atmosphere, and the damage to the cultural inheritance and the economy. The clusters on human and ecosystem exposure are subdivided into exposure to higher concentrations over a short time (smog), and exposure to concentrations averaged over a time-scale of seasons. Exposure of humans in the indoor environment is also treated separately. NTIS

SENSITIVITY OF CLIMATE MODELS: COMPARISON OF SIMULATED AND OBSERVED PATTERNS FOR PAST CLIMATES Progress Report, 1 Feb. 1994 - 31 Jan. 1995

J. Kutzbach, R. J. Oglesby, W. L. Prell, and T. Webb, III Oct. 1994 12 p
(Contract DE-FG02-85ER-60304)
(DE95-002257; DOE/ER-60304/10) Avail: CASI HC A03/MF A01

General circulation models of the atmosphere and oceans are key to the prediction of the potential climate changes that may be induced by increased concentrations of greenhouse gases. Confidence in the predictions of these models can be gained by testing of these models in their ability to simulate past climates. Estimates of global mean temperature change show that the magnitude of warming since the last glacial maximum 21,000 calendar years ago match the magnitude of warming currently being predicted for the doubling of carbon dioxide in the atmosphere. Simulations of the climatic changes for the past 21,000 years as well as for warmer-than-present climates at 6000 and 125,000 years ago provide an excellent opportunity to test the models that are being used in global climate change research. Recognition of this opportunity has been central to our DOE research for the past decade and is now central to PMIP (Paleoclimate Modeling Intercomparison Project) to which our research is contributing. MONITORING THE RESPONSE OF THE UPPER TROPOSPHERE/LOWER STRATOSPHERE TO A GREENHOUSE GAS SCENARIO

J. M. Davis and S. K. Cox 25 Sep. 1994 26 p
(Contract DE-FG02-90ER-60970)
(DE95-000982; DOE/ER-60970/3) Avail: CASI HC A03/MF A01

A measurement system for examining the possible linkage between an increased concentration of Greenhouse Gases (GG's) and symptoms of climate change has been designed and evaluated. The system consists of a dual port emission interferometer and supporting data analysis algorithms for the remote sensing the upper troposphere/lower stratosphere from a high elevation ground site deployment. Two blackbody systems were designed and tested to provide necessary calibration targets for the interferometer. The interferometer was deployed during four different periods at climatologically distinct locations to test the capabilities of the system. Over two hundred spectra were collected in a variety of conditions ranging from a clear middle latitude atmosphere viewed from mountain site at 3.0 km ASL to sub-tropical marine stratocumulus cloudiness measured at Porto Santo Island near Madeira. The algorithm has been used successfully to retrieve temperature and moisture profiles from both the mountain and sea level deployments. These initial retrievals indicate that ground based systems may only be effective in sensing the temperature and moisture profiles for the first few kilometers above the instrument. The interferometric data have been used to estimate the size of 'equivalent spherical' ice particles in cirrus clouds. The data from the sea level deployment were examined in order to retrieve the absorption coefficients of marine stratocumulus clouds and a double iteration algorithm has been developed to deduce the emittance of cirrus clouds from interferometric spectral measurements. POSSIBLE GLOBAL ENVIRONMENTAL IMPACTS OF SOLID WASTE PRACTICES

M. M. Davis, G. M. Holter, T. J. DeForest, D. C. Stapp, and J. C. Dibari (Heritage Coll., Toppenish, WA.) Sep. 1994 67 p
(Contract DE-AC06-76RL-01830)
(DE95-000830; PNL-10149) Avail: CASI HC A04/MF A01

Pollutants resulting from the management of solid waste have been shown to affect the air, land, oceans, and waterways. In addition, solid wastes have other, more indirect impacts such as reduction in feedstocks of natural resources, because useful materials are disposed of rather than recycled. The objective of this study is to evaluate solid waste management practices that have negative implications on the global environment and develop recommendations for reducing such impacts. Recommendations identifying needed changes are identified that will reduce global impacts of solid waste practices in the future. The scope of this study includes the range of non-hazardous solid wastes produced within our society, including municipal solid waste (MSW) and industrial solid waste (ISW), as well as industry-specific wastes from activities such as construction, demolition, and landclearing. Most solid waste management decisions continue to be made and implemented at very local levels, predominantly with a short-term focus to respond to relatively immediate pressures of landfill shortages, funding problems, political considerations, and the like. In this rush to address immediate local problems, little consideration is being given to potential impacts, either short- or long-term, at the national or global level resulting from solid waste management practices. More and more, the cumulative impacts from local decisions concerning solid waste management are beginning to manifest themselves in broader, longer-term impacts than are being addressed by the decision-makers or, at the very least, are presenting a greater and greater potential for such impacts. DOE

ENVIRONMENTAL HAZARDS ASSESSMENT PROGRAM

1994 725 p
(Contract DE-FG01-92EW-50625)
(DE94-019075; DOE/EW-50625/T18-Vol-4) Avail: CASI HC A99/MF A06

The Medical University of South Carolina's (MUSC) vision is to become the premier national resource for medical information and for environmental/health risk assessment. A key component to the success of the many missions of the Environmental Hazards Assessment Program (EHAP) is timely access to large volumes of data. The significant growth in the number of environmental/health information systems that has occurred over the past few years has made data access challenging. This study documents the results of the needs assessment effort conducted to determine the information access and processing requirements of EHAP. The following topics are addressed in this report: immunological consequences of beryllium exposure; assessment of genetic risks to environmental diseases; low dose-rate radiation health effects; environmental risk perception in defined populations; information support and access systems; and environmental medicine and risk communication: curriculum and a professional support network-Department of Family Medicine. SPECTROSCOPIC STUDIES OF HAZARDOUS FUEL INTERACTIONS WITH SOILS Interim Report, Oct. 1989 - Oct. 1990
Terence L. Tipton and Daniel A. Stone Dec. 1993 180 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A279099; ESL-TR-90-47) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This report describes the development and application of techniques for the spectroscopic study of hazardous fuel compounds in soils. The objective is to obtain improved models of bulk pollutant transport through soils. Two approaches have been used for this study: one consists of in-situ measurements of electronic and vibrational interactions via ultraviolet-visible spectroscopy and infrared spectroscopy, respectively; the other incorporates analytical separation techniques to extract contaminants from soils and identify individual reaction products. Initially, montmorillonite clay has been chosen as a prototype soil sample because the structure of this clay is well characterized and spectroscopic results can be readily interpreted. Further simplification has been obtained by exposing the clay samples to individual fuel components rather than mixtures. An interpretation of one clay/fuel system has been accomplished. The plan is to gradually increase the complexity of the samples until typical field conditions can be modeled. DTIC

THE MESSAGE PASSING VERSION OF THE PARALLEL COMMUNITY CLIMATE MODEL
J. B. Drake, R. E. Flanery, D. W. Walker, P. H. Worley, I. T. Foster (Argonne National Lab., IL.), J. G. Michalakes (Argonne National Lab., IL.), R. L. Stevens (Argonne National Lab., IL.), J. J. Hack (National Center for Atmospheric Research, Boulder, CO.), and D. L. Williamson (National Center for Atmospheric Research, Boulder, CO.) 1994 14 p Presented at the 5th ECMWF Workshop on Parallel Processing in Meteorology, Reading, England, 23-27 Nov. 1992 Sponsored in cooperation with NSF
(Contracts DE-AC05-84OR-21400; W-31-109-eng-38)
(DE94-019158; CONF-9211198-3) Avail: CASI HC A03/MF A01

This paper is a brief overview of a parallel version of the NCAR Community Climate Model, CCM2, implemented for MIMD massively parallel computers using a message-passing programming paradigm. The parallel implementation was developed on an Intel iPSC/860 with 128 processors and on the Intel Delta with 512 processors, and the initial target platform for the production version of the code is the Intel Paragon with 2,048 processors. Because the implementation uses a standard, portable message-passing library, the code can be easily ported to other multiprocessors supporting a message-passing programming paradigm, or run on machines distributed across a network. The parallelization strategy used is to decompose the problem domain into geographical patches and assign each processor to do the computation associated with a distinct subset of the patches. With this decomposition, the physics calculations involve only grid points and data local to a processor and are performed in parallel. Using parallel algorithms developed for the semi-Lagrangian transport, the fast Fourier transform and the Legendre transform, both physics and dynamics are computed in parallel with minimal data movement and modest change to the original CCM2 source code. DOE

REMOVAL OF CO2 IN CLOSED LOOP OFF-GAS TREATMENT SYSTEMS
M. K. Clemens, P. A. Nelson, and W. M. Swift 1994 23 p Presented at the 6th Emerging Technologies in Hazardous Waste Management, Atlanta, GA, 19-21 Sep. 1994
(Contract W-31-109-eng-38)
(DE94-019259; ANL/CMT/CP-82692; CONF-9409215-1) Avail: CASI HC A03/MF A01

A closed loop test system has been installed at Argonne National Laboratory (ANL) to demonstrate off-gas treatment, absorption, and purification systems to be used for incineration and vitrification of hazardous and mixed waste. Closed loop systems can virtually eliminate the potential for release of hazardous or toxic materials to the atmosphere during both normal and upset conditions. In initial tests, a 250,000 Btu/h (75 kW thermal) combustor was operated in an open loop to produce a combustion product gas. The CO2 in these tests was removed by reaction with a fluidized bed of time to produce CaCO3. Subsequently, recirculation system was installed to allow closed loop operation with the addition of oxygen to the recycle stream to support combustion. Commercially marketed technologies for removal of CO2 can be adapted for use on closed loop incineration systems. The paper also describes the Absorbent Solution Treatment (AST) process, based on modifications to commercially demonstrated gas purification technologies. In this process, a side loop system is added to the main loop for removing CO2 in scrubbing towers using aqueous-based CO2 absorbents. The remaining gas is returned to the incinerator with oxygen addition. The absorbent is regenerated by driving off the CO2 and water vapor, which are released to the atmosphere. Contaminants are either recycled for further treatment or form precipitates which are removed during the purification and regeneration process. There are no direct releases of gases or particulates to the environment. The CO2 and water vapor go through two changes of state before release, effectively separating these combustion products from contaminants released during incineration. The AST process can accept a wide range of waste streams. The system may be retrofitted to existing Facilities or included in the designs for new installations. DOE

SELECTION OF SUBSTANCES TO BE CONSIDERED IN THE ENVIRONMENTAL BALANCE/ENVIRONMENTAL OUTLOOK IN RELATION TO THE DISSEMINATION THEME [STOFKEUZE VOOR HET THEMA VERSPREIDING IN DE MILIEUBALANS/MILIEUVERKENNING]
W. Slooff Apr. 1994 57 p In DUTCH
(PB95-132197; RIVM-482516002) Avail: Issuing Activity (National Technical Information Service (NTIS))

This report presents a proposal on a selection of substances, to be considered in the Environmental Balance/Environmental Outlook in relation to the Dissemination theme. As a first step in the selection procedure it was decided to exclude new substances, notified prior to their introduction on the market; substances that also are considered within other policy themes, except for those compounds that exceed toxicological risk levels; genetically modified organisms; biological agents; and cleaning up contaminated soils. As a second step a number of criteria (relevance, knowledge, controllability) was applied to policy based lists of substances. NTIS

IMPLEMENTATION OF ELECTRONIC CHAIN-OF-CUSTODY, ANALYSIS REQUESTS, AND DATA VERIFICATION AT LOS ALAMOS NATIONAL LABORATORY
H. C. Pound and J. J. Miglio 1994 13 p Presented at the American Society for Quality Control Energy and Environmental Quality Division Conference, Tucson, AZ, 18-21 Sep. 1994
(Contract W-7405-eng-36)
(DE94-018076; LA-UR-94-2694; CONF-940985-7) Avail: CASI HC A03/MF A01

To improve the efficiency of the entire environmental data collection process from sample collection to reporting to the client, Los Alamos National Laboratory is developing an automated system to carry out as much of the process as possible. The system uses 'off-the-shelf' software. Our program anticipates a drastic reduction of the amount of paper generated throughout the process. The electronic system includes spreadsheets used for field and laboratory chains-of-custody. In addition, the system is used to order analyses and to verify data for compliance. DOE

ENVIRONMENTAL CLEANUP: TOO MANY HIGH PRIORITY SITES IMPEDE DOD'S PROGRAM. REPORT TO THE CHAIRMAN, COMMITTEE ON GOVERNMENTAL AFFAIRS, US SENATE
Apr. 1994 28 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(AD-A279511; GAO/NSIAD-94-133; B-256676) Avail: Issuing Activity (Defense Technical Information Center (DTIC)); GAO, PO Box 6015, Gaithersburg, MD 20884-6015 HC

Military installations are similar to small cities in term of population, industrial activities, and some types of contaminated sites, However, some cover an area larger than a small state. DOD has operated industrial facilities on its installations for several decades that have generated, stored, recycled, or disposed of hazardous wastes. Many of these activities have contaminated the nearby soil and groundwater. To study and clean up contaminated sites, DOD established the Installation Restoration Program (IRP) in 1975. In 1984, the IRP was made part of the Defense Environmental Restoration Program. DTIC

OHMSETT TEST OF NOFI VEE-SWEEP AND NOFI 600S OILBOOM Final Report

Michael J. Goodwin Oct. 1993 122 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract DOT-CG-14-35-0001-30544)
(AD-A279525; USCG-D-04-94; CGR/DC-22/93) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

A NOFI Vee-Sweep and a NOFI 600S Oilboom, both manufactured by NOFI TROMSO A/S of Norway, were tested at the Ohmsett test tank in Leonardo, NJ. The V-Shaped Sweep is an oil boom designed for use with a skimmer at the apex of the V-Shaped configuration. Oil is funneled back to the skimmer by the converging sides of the V and concentrated for more efficient skimming. The 60 meter length of the sweep is doubled over to form the V and held in this shape by cross netting at the bottom of the skirt. The bottom netting is claimed to help stabilize the oil in the sweep. The sweep was towed with a 700 mm skirt depth and mouth opening of 16 meters. The mouth opening was reduced from the designed 19.8 meters to fit in the tow tank without causing excess blockage. The limiting towing speeds of the sweep were determined with and without oil present, in calm water and in small waves. The sweep's ability to conform to waves was also determined. Towing forces were measured. Limited data on oil loss rates were obtained. Testing confirmed the manufacturer's claim that the sweep can be towed at 1.0 and 1.4 knots with oil in calm water, based on the first loss of oil. The critical tow speed was found to be 3.4 to 3.6 knots in calm water. DTIC

ENVIRONMENTAL COMPLIANCE ASSESSMENT AND MANAGEMENT PROGRAM (ECAMP), SOUTH CAROLINA SUPPLEMENT Interim Report

Carolyn ORourke and Lisa A. Gifford Apr. 1994 311 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A279533; CERL-SR-EC-94/16) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The number of environmental laws and regulations has continued to grow in the United States and worldwide, making compliance with these regulations increasingly difficult. Environmental assessments became a way to determine compliance with current environmental regulations. The U.S. Air Force has adopted an environmental compliance program that identifies compliance problems before they are cited as violations by the U.S. Environmental Protection Agency (USEPA). Beginning in 1984, the U.S. Army Construction Engineering Research Laboratories (USACERL), in cooperation with the Air Force Engineering and Services Center, began research on the U.S. Environmental Compliance Assessment and Management Program (ECAMP). The concept was to combine Federal, Department of Defense (DOD), and Air Force environmental regulations, along with existing checklists from the USEPA and private industry, and documentation of good management practices and risk-management issues, into a series of checklists that list legal requirements and specify items or operations to review. Each assessment protocol lists a point of contact to help assessors review the checklists as effectively as possible. The South Carolina Supplement was developed to be used in conjunction with the U.S. ECAMP manual, using existing South Carolina state environmental legislation and regulations as well as suggested management practices. ENVIRONMENTAL COMPLIANCE ASSESSMENT SYSTEM (ECAS): OREGON SUPPLEMENT Final Report

Carolyn ORourke and Lisa A. Gifford Apr. 1994 55 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A279565; CERL-SR-EC-94/18) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

In response to the growing number of environmental laws and regulations worldwide, the U.S. Army has adopted an environmental compliance program that identifies compliance problems before they are cited as violations by the U.S. Environmental Protection Agency (USEPA). Beginning in 1985, Major Army Commands (MACOM's) were required to conduct comprehensive environmental assessments at all installations on a 4-year cycle. The installations must also conduct a mid-cycle internal assessment. Because each MACOM was developing a separate assessment system, the Army mandated, through Army Regulation 200-1, one unified Army-wide assessment mechanism. The resulting system combines Federal, Department of Defense (DOD), and Army environmental regulations, along with good management practices and risk management information, into a series of checklists that show legal requirements and specific items or operations to review. Each assessment protocol lists a point of contact to help assessors review the checklist items as effectively as possible. The Environmental Compliance Assessment System (ECAS) manual incorporates existing checklists from USEPA and private industry. The Oregon Supplement was developed to be used in conjunction with the U.S. ECAS manual, using existing Oregon state environmental legislation and regulations as well as suggested management practices. COMPILATION OF 1993 ANNUAL REPORTS OF THE NAVY ELF COMMUNICATIONS SYSTEM ECOLOGICAL MONITORING PROGRAM Annual Report, Jan. - Sep. 1993

J. E. Zapotosky Apr. 1994 410 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00039-93-C-0001)
(AD-A279575) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

During 1993, the U.S. Navy continued to conduct a program to monitor flora, fauna, and their ecological relationships for possible effects from electromagnetic (EM) fields produced by the Navy's Extremely Low Frequently (ELF) Communications System. Physiological, developmental, behavioral, and ecological variables for dominant biota in upland and riverine habitats near the Naval Radio Transmitting Facility at Republic, Michigan (NRTF-Republic) have been monitored since 1982. The NRTF-Republic was intermittently energized at low amperages beginning in early 1986. Electric current and periods of energization were then gradually increased until 1989, when the transmitter became a fully operational facility. A split-plot or blocked strategy was used to examine biological variables for possible effects from EM exposure. Reports complied in this document present the progress of these studies through 1993. Final results and conclusions are expected after all data have been analyzed in 1994. Investigators for similar studies completed in Wisconsin concluded that there were no EM bioeffects from intermittent or full operation of the transmitter in that state. DTIC

MODELING THE RESPONSE OF THE CALIFORNIA CURRENT SYSTEM TO GLOBAL GREENHOUSE WARMING

A. Pares-Sierra and R. C. J. Somerville 1993 7 p
(Contract DE-FC03-90ER-61010)
(DE94-018253; DOE/ER-61010/T26) Avail: CASI HC A02/MF A01

This is the final report for the project 'Modeling the Response of the California Current System to Global Greenhouse Warming,' supported 1990 and 1991 by NIGEC. The scientists involved are Dr. Richard C.J. Somerville and Alejandro Paries-Sierra of Scripps Institution of Oceanography, UCSD. A copy of papers submitted to the Journal of Physical Oceanography, and Geofisica Internacional that were supported in part or whole by WEST-GEC, as well as a summary of a talk delivered at the 20th General Assembly of the IUGG, Vienna are appended to this report. The objective of the research was to improve the understanding of the response of the California Current system to the large-scale anomalous forcing thought to be associated with greenhouse warming. The authors viewed this as a necessary initial step in the study of the California climate response to global change. DOE

AIR POLLUTION CAUSED BY FIREWORKS DURING THE TURN OF THE YEAR 1992-1993 [LUCHTVERONTREINIGING DOOR VUURWERK TIJDENS DE JAARWISSELING VAN 1992-1993]

H. Noordijk Apr. 1993 56 p In DUTCH
(PB95-135265; RIVM-722103001) Avail: Issuing Activity (National Technical Information Service (NTIS))

Various meteorological conditions, especially the presence of a very low and strong temperature inversion and the absence of wind, caused a sharp increase of atmospheric pollutants during the festivities at the turn of the year 1992. The major components of the particles are carbonates, sulfates and chlorides of potassium. The average concentration of metals in cities in the first hour of the new year is estimated to be about 100 - 1,000 micrograms/cu m. Salts of aluminum and magnesium predominate. Minor contributions are observed for strontium, barium and lead. Contributions of other metals are very low or not observed. Other compounds, such as nitrogen oxides, sulfur dioxide and carbon monoxide, did not noticeably increase after the fireworks. The high concentration of fine particles may have caused acute health effects, such as tightness of the chest. Especially people with chronic lung or pulmonary diseases may have experienced troubles. Visibility was reduced due to scattering by the released particles, in combination with moisture in the air. Visibility in or near domestic areas has been reduced to several tens of meters in the first hours of the new year. Locally, further visibility reductions, due to fireworks and fires, are expected. Extreme visibility reductions have been observed indeed. NTIS

OZONE-DEPLETING-SUBSTANCE CONTROL AND PHASE-OUT PLAN

J. M. Nickels and M. J. Brown Jul. 1994 65 p
(DE95-001647; DOE/RL-94-86) Avail: CASI HC A04/MF A01

Title VI of the Federal Clean Air Act Amendments of 1990 requires regulation of the use and disposal of ozone-depleting substances (ODS's) (e.g., Halon, Freon). Several important federal regulations have been promulgated that affect the use of such substances at the Hanford Site. On April 23, 1993, Executive Order (EO) 12843, Procurement Requirements and Policies for Federal Agencies for Ozone-Depleting Substances (EPA 1993) was issued for Federal facilities to conform to the new US Environmental Protection Agency (EPA) regulations implementing the Clean Air Act of 1963 (CAA), Section 613, as amended. To implement the requirements of Title VI the US Department of Energy, Richland Operations Office (RL), issued a directive to the Hanford Site contractors on May 25, 1994 (Wisness 1994). The directive assigns Westinghouse Hanford Company (WHC) the lead in coordinating the development of a sitewide comprehensive implementation plan to be drafted by July 29, 1994 and completed by September 30, 1994. The implementation plan will address several areas where immediate compliance action is required. It will identify all current uses of ODS's and inventories, document the remaining useful life of equipment that contains ODS chemicals, provide a phase-out schedule, and provide a strategy that will be implemented consistently by all the Hanford Site contractors. This plan also addresses the critical and required elements of Federal regulations, the EO, and US Department of Energy (DOE) guidance. This plan is intended to establish a sitewide management system to address the clean air requirements. DOE

DEFINITION REPORT ON TARGET AND RELATED STEERING VARIABLES OF RADIATION AS A PART OF THE ENVIRONMENTAL BALANCE AND ENVIRONMENTAL OUTLOOK INVESTIGATION [DEFINITIERAPPORT: GRAADMETERS STRALING IN DE MILI EUBALANS/MILIEUVERKENNING]

M. J. M. Pruppers, F. J. Aldenkamp, R. O. Blaauboer, G. J. Eggink, and P. J. M. Kwakman Feb. 1994 40 p In DUTCH
(PB95-135471; RIVM-610055001) Avail: Issuing Activity (National Technical Information Service (NTIS))

This definition report describes the elaboration of this approach when it is applied to the complete area of interest 'radiation'. Together with other definition reports it is supposed to be the justification of choices which are made in defining the sequence of subjects and the minimum set of variables. The elaboration is guided by the policy document 'Radiation protection and risk management'. The policy can be characterized as 'risk management by focusing directly on the sources of radiation'. In other words steering at the beginning and setting limits at the end of the source-risk-chain. Therefore, in the report it is concluded that the complete source-risk-chain has to be analyzed and modelled. NTIS

AQUATIC PLANT CONTROL RESEARCH PROGRAM. ECOLOGICAL ASSESSMENT OF KIRK POND Final Report

John D. Madsen, Gary O. Dick, David Honnell, Judy Shearer, and R. M. Smart Mar. 1994 75 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A279090; WES/MP/EL-A-94-1) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Kirk Pond is a 24-ha man-made pond adjacent to Fern Ridge Reservoir, OR. It is the central feature of Kirk Park, a multiple day-use park at the project. Kirk Pond supports a naturally reproducing warmwater fishery and a put-and-take trout fishery. For many years, the pond has been impacted by dense growths of Eurasian watermilfoil (Myriophyllum spicatum L.), which has greatly restricted recreational use of the pond and threatens both the native plants and vigor of the fishery. The primary purpose of this study was to provide an ecological assessment of the pond in preparation for an experimental application of the potential biological control agent Mycoleptodiscus terrestris (Mt), marketed as the mycoherbicide Aqua-Fyte. The primary goals of the assessment were to (1) determine the role of environmental factors, such as water depth, sediment and water chemistry, and light availability in affecting the present and future distribution and abundance of submersed aquatic plants (particularly M. spicatum) in Kirk Pond; (2) assess the condition of the Kirk Pond ecosystem, including water quality as well as the distribution, abundance, and species diversity of fish populations; and (3) document the existence of any endemic populations of the pathogenic fungus Mycoleptodiscus terrestris. DTIC

TRANSPORT, RADIATIVE, AND DYNAMICAL EFFECTS OF THE ANTARCTIC OZONE HOLE: A GFDL SKYHI MODEL EXPERIMENT

J. D. Mahlman, J. P. Pinto, and L. J. Umscheid 15 Feb. 1994 24 p See also PB88-168240 Submitted for publication Prepared in cooperation with NOAA, Princeton, NJ Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(PB94-192754; EPA/600/J-94/308) Avail: Issuing Activity (National Technical Information Service (NTIS))

The Geophysical Fluid Dynamics Laboratory 'SKYHI' general circulation model has been used to simulate the effect of the Antarctic 'ozone hole' phenomenon on the radiative and dynamical environment of the lower stratosphere. Both the polar ozone destruction and photochemical restoration chemistries are calculated by parameterized simplifications of the still uncertain more complete chemical processes. The modeled total column ozone depletions are near 25% in spring over Antarctica, with 1% depletion reaching equatorial latitudes by the end of the 4 and 1/2 year model experiment. In the lower stratosphere, ozone reductions of 5% reach to the equator. Large coolings of about 8 C are simulated in the lower stratosphere over Antarctica in late spring, while a general cooling of about 1-1.5 C is present throughout the Southern Hemisphere's lower stratosphere. The model atmosphere experiences a long-term positive temperature-chemical feedback because significant ozone reductions carry over into the next winter. The overall temperature response to the reduced ozone is essentially radiative in character. However, substantial dynamical changes are induced by the ozone hole effect. The Antarctic middle stratosphere in late spring warms by about 6 C over Antarctica and the lower mid-latitude stratosphere warms by approximately one degree. These warming spots are produced mainly by an increased residual circulation intensity. NTIS

INITIAL ASSESSMENT OF THE HAZARDS AND RISKS OF NEW CHEMICALS TO MAN AND THE ENVIRONMENT, PART 2

T. G. Vermeire, G. W. Kroese, G. R. Meijer, J. Mohn, and W. J. G. M. Notenboom May 1993 79 p See also PB93-178184
(PB95-106407; RIVM-679102018) Avail: Issuing Activity (National Technical Information Service (NTIS))

This report is a continuation of the description of the initial hazard and risk assessment process for new substances at the National Institute of Public Health and Environmental Protection (RIVM) in The Netherlands. The present publication pertains to the post base set assessment, specifically on the basis of tests required at market volumes of 100 to 1000 tons per year or 500 to 5000 tons cumulative (level 1). It has primarily been written as a reference guide for those involved in the hazard and risk assessment process at RIVM, but also for risk managers responsible for the regulation and the overall dossier evaluation of new substances, and for others interested in this subject, e.g. industry, nongovernmental organizations, and the public at large. DERIVATION OF PRELIMINARY MAXIMUM PERMISSIBLE CONCENTRATIONS OF VOLATILE COMPOUNDS IN AIR

B. C. Rademaker, E. P. Guinee, and E. J. vandePlassche Jul. 1993 114 p
(PB95-107447; RIVM-679101-009) Avail: CASI HC A06/MF A02

In the sub-project 'Volatile Compounds', part of the project 'Setting integrated environmental quality objectives', maximum permissible concentrations (MPC's) are derived for 46 volatile substances for water, sediment, soil, and air. These MPC's are used for setting integrated environmental quality objectives (i.e., limit and target values). In case of the derivation of MPC's in air a step-wise approach was used. First, preliminary MPC's are derived based on information from reviews only. These preliminary MPC's will be harmonized with the ones for water, sediment, and soil. If it can be concluded that the preliminary MPC in air leads to exceedance of a MPC in another compartment, the preliminary MPC in air will be reevalauted. The present report contains the results of the derivation of these preliminary MPC's. Therefore preliminary MPC's in air were derived aiming at the protection of man as well as the ecosystem: the MPC(sub human) and MPC(sub eco), respectively. Both MPC's are compared and one will be selected as the preliminary MPC in air used for harmonization. NTIS

ENVIRONMENTAL COMPLIANCE ASSESSMENT SYSTEM (ECAS): JAPAN SETTLEMENT Final Report

David A. Krooks and Tina M. Hurt Dec. 1993 228 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract MIPR-0823)
(AD-A279328; CERL-SR-EC-94/05) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The U.S. Army has adopted an environmental compliance program that identifies compliance problems before they are cited as violations by the U.S. Environmental Protection Agency (USEPA). Major Army Commands (MACOMs) must conduct comprehensive environmental assessments at all installations on a 4-year cycle and conduct a mid-cycle internal assessment. Because each MACOM developed a separate system, the Army mandated a unified, Army-wide assessment mechanism, which combines Federal, Department of Defense (DOD), and Army environmental regulations; good management practices; and risk-management issues into a series of checklists that show requirements and specific items or operations to review. Each protocol lists a point of contact to help assessors review checklist items. The Worldwide Environmental Compliance Assessment System (ECAS) manual incorporates checklists from USEPA and from private industry. It integrates information from the Overseas Environmental Baseline Guidance Document (OEBGD). Worldwide ECAS includes pertinent information from Army Regulations and DOD Directives and Instructions and cites management practices for an overall environmental review. The ECAS JAPAN supplement incorporates Japanese legislation, regulations, and suggested management practices. It was developed for use in conjunction with the Worldwide ECAS manuals (USACERL SR-EC-93/03) and is updated continually to address changes in Japanese laws and regulations. DTIC

ASSESSMENT OF THE ATMOSPHERIC HAZARDS AND RISKS OF NEW CHEMICALS: PROCEDURES TO ESTIMATE HAZARD POTENTIALS

F. A. A. M. deLeeuw Mar. 1993 26 p See also PB93-178168
(PB95-107488; RIVM-679102017) Avail: CASI HC A03/MF A01

A procedure for the assessment of atmospheric hazards and risks of newly introduced chemicals is discussed. However, an assessment of direct effects caused by exposure to expected ambient concentrations or by deposition is not discussed; here emphasis is on the role which new substances might play in the atmosphere. Procedures to estimate 'hazard potentials' to quantify the potential risk of a new substance in atmosphere-related environmental problems are proposed. In particular, hazard potentials for the following topics are defined: global warming; ozone depletion; photochemical smog formation; and acidification and eutrophication. NTIS

GAS-PHASE PHOTOCATALYTIC OXIDATION: COST COMPARISON WITH OTHER AIR POLLUTION CONTROL TECHNOLOGIES

Craig S. Turchi, Edward J. Wolfrum, and Richard A. Miller (IT Corp., Knoxville, TN.) Nov. 1994 6 p Presented at the 1st International Conference on Advanced Oxidation Technologies for Water and Air Remediation, London, Ontario, 25-30 Jun. 1994
(Contract DE-AC36-83CH-10093)
(DE95-000241; NREL/TP-471-7014; CONF-9406143-2) Avail: CASI HC A02/MF A01

Gas-phase photocatalytic oxidation (PCO) appears to be particularly well suited for waste streams with low pollutant concentrations (1,000 ppm or less) and low to moderate flow rates (less than 20,000 cu ft/min, cfm). The PCO technology is modular in nature and thus is well suited to treat dispersed or low flow rate streams. This same attribute minimizes the advantages of scale for PCO and makes the technology comparatively less attractive for high volume waste streams. Key advantages for PCO lie in its low operating cost and ability to completely destroy pollutants at ambient temperature and pressure. The photocatalytic oxidation process destroys organic air pollutants at ambient temperature and pressure through the use of a light-excited titanium dioxide catalyst. It is being developed for the treatment of industrial emissions, site remediation, and indoor air quality. The objective of this study is to compare PCO costs to those for other common means of treating volatile organic compounds (VOCs) in air. DOE

USE OF THE CARBO-FLO PROCESS TO PURIFY PROCESS WATER CONTAMINATED BY AGRICULTURAL PESTICIDES

M. Maaskant, E. vanDullemen, R. Ronday, A. J. Zweers, and H. Perebolte 1994 156 p
(PB95-127825) Copyright Issuing Activity (National Technical Information Service (NTIS))

The objective of the project is to reduce substantially contamination of surface water by pesticides as a result of the discharge of process water from the agricultural and horticultural sectors. The purification efficiency of the Carbo-Flo process has been studied in nine important agricultural and horticultural sectors. Chemical and toxicological analyses show that a high degree of purification is possible using the Carbo-Flo process. For the collection and storage of unused spray and washings, the infrastructure at farm level needs to be adapted. For large-scale introduction, processing plants with a capacity of 5-10 cubic meters per day are a good option from the point of view of treatment costs, licenses, and quality control. NTIS

MICROMETEOROLOGICAL METHODS FOR MEASUREMENTS OF MERCURY EMISSIONS OVER CONTAMINATED SOILS

K. H. Kim, S. E. Lindberg, P. J. Hanson, J. Owens, and T. P. Myers (National Oceanic and Atmospheric Administration, Oak Ridge, TN.) 1993 5 p Presented at the 1st Workshop on Emissions and Modelling of Atmospheric Transport of Persistent Organic Pollutants and Heavy Metals, Durham, NC, 6-7 May 1993
(Contract DE-AC05-84OR-21400)
(DE94-017679; CONF-9305320-2) Avail: CASI HC A01/MF A01

As part of a larger study involving development and application of field and laboratory methods (micrometeorological, dynamic enclosure chamber, and controlled laboratory chamber methods) to measure the air/surface exchange of Hg vapor, we performed a series of preliminary measurements over contaminated soils. From March - April 1993, we used the modified Bowen ratio (MBR) method to measure emission rates of mercury over a floodplain contaminated with mercury near Oak Ridge, TN. The mercury emission rates measured from contaminated EFPC soils using the MBR method during early spring show that: (1) in all cases, the contaminated soils acted as a source of mercury to the atmosphere with source strengths ranging from 17 to 160 ng m(exp -2) h(exp -1); and (2) the strengths of mercury emissions can be greatly influenced by the combined effects of surface soil temperature, residence time of air masses over the source area, and turbulence conditions. The mercury fluxes measured in a controlled flow chamber indicate that contaminated soils can exhibit up to an order of magnitude higher emission rates of Hg under conditions of elevated soil temperature, soil structure disturbance, and high turbulence. Mercury emissions from contaminated soils exceeded emissions from background soils by one to two orders of magnitude. DOE

DERIVATION OF MAXIMUM PERMISSIBLE CONCENTRATIONS FOR SEVERAL VOLATILE COMPOUNDS FOR WATER AND SOIL

E. J. vandePlassche, M. D. Polder, and J. H. Canton May 1993 142 p
(PB95-107454; RIVM-679101-008) Avail: CASI HC A07/MF A02

In this report Maximum Permissible Concentrations (MPC's) for water, sediment and soil were derived for 46 volatile organic compounds in frame of the project 'Volatile compounds'. This project is part of another one called 'Setting integrated environmental quality objectives'. Because most of the 46 compounds are acting by narcosis the QSAR (Quantitative Structure-Activity Relationships) approach from Van Leeuwen et al. (1992) is used in order to derive MPC's for water. This approach uses NOEC values obtained by application of QSAR's for minimum toxicity for 19 different organisms. These NOEC values are used as input data for the extrapolation method of Aldenberg and Slob to calculate a MPC. Toxicity data for soil organisms were gathered from literature. Due to scarcity of data only for 11 compounds a MPC for soil could be derived. In all cases the modified EPA method had to be applied. No toxicity data were available for benthic organisms exposed via contaminated sediment. NTIS

VELOCITY ANALYSIS FOR TRANSVERSELY ISOTROPIC MEDIA

T. Alkhalifah and I. Tsvankin Aug. 1994 62 p Presented at the CWP Annual Project Review Meeting, Breckenridge, CO, 11-14 May 1993
(Contract DE-FG02-89ER-14079)
(DE95-000643; DOE/ER-14079/32; CWP-145P; CONF-9305377-2) Avail: CASI HC A04/MF A01

The main difficulty in extending seismic processing to anisotropic media is the recovery of anisotropic velocity fields from surface reflection data. Velocity analysis for transversely isotropic (TI) media can be done by inverting the dependence of P-wave moveout velocities on the ray parameter. P-wave NMO velocity in homogeneous TI media with a vertical symmetry axis depends just on the zero-dip value V(sub nmo) and a new effective parameter (eta) that reduces to the difference between Thomsen parameters (epsilon) and (delta) in the limit of weak anisotropy. It is possible to obtain (eta) and reconstruct the NMO velocity as a function of ray parameter using moveout velocities for two different dips. Moreover, V(sub nmo)(0) and (eta) determine not only the NMO velocity, but also also long-spread (nonhyperbollic) P-wave moveout for horizontal reflectors and time-migration impulse response. Inversion of dip-moveout information allows performance of all time-processing steps in TI media using only surface P-wave data. Isotropic time-processing methods remain entirely valid for elliptical anisotropy (epsilon = delta). Accurate time-to-depth conversion, however, requires the vertical velocity V(sub P0) be resolved independently. If I-P0 is known, then all isotropies (epsilon) and (delta) can be found by inverting two P-wave NMO velocities corresponding to a horizontal and a dipping reflector. If no information is available, all three parameters (V (sub P0), (epsilon), and (delta)) can be obtained by combining inversion results with shear-wave information. such as the P-SV or SV-SV wave NMO velocities for a horizontal reflector. Generalization of Tsvankin's single-layer NMO equation for layered anisotropic media with a dipping reflector provides a basis for extending anisotropic velocity analysis to vertically inhomogeneous media. The influence of a stratified overburden on moveout velocity can be stripped through a Dix-type differentiation procedure. DOE

P-WAVE SIGNATURES AND PARAMETERIZATION OF TRANSVERSELY ISOTROPIC MEDIA: AN OVERVIEW

I. Tsvankin Jul. 1994 51 p Presented at the CWP Annual Project Review Meeting, Breckenridge, CO, 11-14 May 1993
(Contract DE-FG02-89ER-14079)
(DE95-000644; DOE/ER-14079/33; CWP-152P; CONF-9305377-1) Avail: CASI HC A04/MF A01

Progress in seismic inversion and processing in anisotropic media depends on our ability to relate different seismic signatures to the anisotropic parameters. While the conventional notation (stiffness coefficients) is suitable for forward modeling, it is inconvenient in developing analytic insight into the influence of anisotropy on wave propagation. The author gives a consistent description of P-wave signatures in transversely isotropic media with arbitrary strength of the anisotropy, using the notation suggested by Thomsen (1986). The influence of transverse isotropy on P-wave propagation is shown to be practically independent of the vertical S-wave velocity V(sub S0), even in models with strong velocity variations. Therefore, the contribution of transverse isotropy to P-wave kinematic and dynamic signatures is controlled by just two anisotropic parameters, (epsilon) and (delta), with the vertical velocity V(sub P0) being no more than a scaling coefficient in homogeneous models. A COMPARATIVE SURVEY OF CURRENT AND PROPOSED TROPOSPHERIC REFRACTION-DELAY MODELS FOR DSN RADIO METRIC DATA CALIBRATION Survey and Evaluation Report
J. A. Estefan (State Univ. of New York, Buffalo, NY.) and O. J. Sovers Oct. 1994 62 p
(Contract NAS7-918)
(NASA-CR-197338; JPL-Publ-94-24; NAS 1.26:197338) Avail: CASI HC A04/MF A01

The standard tropospheric calibration model implemented in the operational Orbit Determination Program is the seasonal model developed by C. C. Chao in the early 1970's. The seasonal model has seen only slight modification since its release, particularly in the format and content of the zenith delay calibrations. Chao's most recent standard mapping tables, which are used to project the zenith delay calibrations along the station-to-spacecraft line of sight, have not been modified since they were first published in late 1972. This report focuses principally on proposed upgrades to the zenith delay mapping process, although modeling improvements to the zenith delay calibration process are also discussed. A number of candidate approximation models for the tropospheric mapping are evaluated, including the semi-analytic mapping function of Lanyi, and the semi-empirical mapping functions of Davis, et. al.('CfA-2.2'), of Ifadis (global solution model), of Herring ('MTT'), and of Niell ('NMF'). All of the candidate mapping functions are superior to the Chao standard mapping tables and approximation formulas when evaluated against the current Deep Space Network Mark 3 intercontinental very long baselines interferometry database. COMPLETION OF SPECTRAL ROTATING SHADOWBAND RADIOMETERS AND ANALYSIS OF ARM SPECTRAL SHORT-WAVE DATA
J. Michalsky and L. Harrison 18 Jul. 1994 17 p
(Contract DE-FG02-90ER-61072)
(DE95-000602; DOE/ER-61072/9) Avail: CASI HC A03/MF A01

Our ARM goal is to help improve both longwave and shortwave models used in GCM's by providing improved radiometric shortwave data. The inference of cloud cover and optical properties of clouds is another goal of this research effort. At the Atmospheric Sciences Research Center (ASRC) in Albany, New York, we are acquiring downwelling shortwave, including direct and diffuse irradiance, at six wavelengths, plus downwelling longwave, upwelling and downwelling broadband shortwave, and aerosol optical depth that we combine with National Weather Service surface and upper air data as a model test data set for ARM researchers. The major objective of our program has been to develop two spectral versions of the rotating shadowband radiometer (RSR). The multi-filter rotating shadowband radiometer (MFRSR) contains six filtered, narrow-passband detectors, and one unfiltered silicon detector that serves as a surrogate total shortwave sensor. The rotating shadowband spectroradiometer (RSS) contains a 256-channel diode array that spans the wavelengths 350-1050 nm with resolution varying between 0.6 nm and 8 nm. With some of the instrument development complete we are devoting more effort to analysis of the MFRSR data. Progress was made on several fronts this year, resulting in conference papers and submissions to refereed journals. Data from the ASRC roof has been used to develop corrections of the MFRSR shortwave sensor. SGP data has been used to develop and validate a retrieval technique for total column water vapor. Total column ozone has been estimated using MFRSR data, but validation at the SGP was not possible for lack of a suitable ozone column standard. Some progress has been made on cloud cover detection, but it is not yet implemented as a routine classification and reporting procedure. DOE

Hakes (Lockheed Engineering and Sciences Co., Houston, TX.) 1993 44 p Presented at the 3d Long Duration Exposure Flight (LDEF) Symposium, Williamsburg, VA, 8-12 Nov. 1993 Submitted for publication
(Contract W-7405-eng-36)
(NASA-TM-110129; NAS 1.15:110129; DE94-009365; LA-UR-94-897; CONF-9311137-2) Avail: CASI HC A03/MF A01

The flight experiment was developed to obtain benchmark atomic oxygen reactivity data and was conducted during Space Transportation System Mission 46 (STS 46), July 31 to August 7, 1992. In this paper, we present an overview of EOIM-III and the results of the materials reactivity and mass spectrometer/carousel experiments. Mass spectrometer calibration methods are discussed briefly, as a prelude to a detailed discussion of the mass spectrometric results produced during STS-46. Mass spectrometric measurements of ambient O-atom flux and fluence are in good agreement with the values calculated using the MSIS-86 model of the thermosphere as well as estimates based on the extent of O-atom reaction with Kapton polyimide. Mass spectrometric measurements of gaseous products formed by O-atom reaction with C(sup 13) labeled Kapton revealed CO, CO2, H2O, NO and NO2. By operating the mass spectrometer so as to detect naturally occurring ionospheric species, we characterized the ambient ionosphere and detected the gaseous reaction products formed when ambient ions interacted with the C(sup 13) Kapton carousel sector. By direct comparison of the results of on-orbit O-atom exposures with those conducted in ground-based laboratory systems, we have demonstrated the strong translational energy dependence of O-atom reactions with a variety of polymers. A 'line-of-centers' reactive scattering model was shown to provide a reasonably accurate description of the translational energy dependence of polymer reactions with O atoms over a three order-of-magnitude range in translational energy and a four order-of-magnitude range in reaction efficiency. Postflight studies of the polymer samples by x-ray photoelectron spectroscopy and infrared spectroscopy demonstrate that O-atom attack is confined to within 50 to 100 Angstroms of the surface. DOE

INVESTIGATING THE RESOLUTION OF RESISTIVITY ARRAYS USING INVERSE THEORY

L. P. Beard and A. C. Tripp (Utah Univ., Salt Lake City, UT.) 1994 14 p Presented at the Symposium on the Application of Geophysics to Environmental and Engineering Problems, Boston, MA, 27-31 Mar. 1994
(Contract DE-AC05-84OR-21400)
(DE94-017760; CONF-940353-8) Avail: CASI HC A03/MF A01

We used a fast 2-D minimum structure inverse solution to examine the ability of different resistivity arrays to resolve structures given noisy synthetic data. We found that the resistivity models obtained from it inversion of the dipole-dipole data were usually very similar to the estimated models from pole-dipole data, and both were superior to estimated models from pole-pole data. This is because noisy dipole-dipole or pole-dipole data define geoelectric structures much more precisely than an equivalent set of noisy pole-pole data. One structure where the dipole-dipole array appeared decidedly superior was the prism beneath a conductive overburden. The final estimated models from the pole-pole data were more poorly resolved than the final models from the other arrays. Our results show that the pole-pole data is a poor choice if vertical resolution of a geoelectric structure is crucial. Furthermore, if pole-pole data contains even a fraction of a percent of noise, the transformation of such data through superposition to equivalent data of other array types is virtually impossible, and significant information is lost. DOE

RADIATIVE FORCING FOR CHANGES IN TROPOSPHERIC O3
A. S. Grossman, D. J. Wuebbles, and K. E. Grant Jun. 1994 7 p
(Contract W-7405-eng-48)
(DE94-019017; UCRL-ID-118063) Avail: CASI HC A02/MF A01

We have evaluated the radiative forcing for assumed changes in tropospheric O3 in the 500-1650 cm(exp -1) wavenumber range. The radiative forcing calculations were performed as a function of latitude as well as for a globally and seasonally averaged model atmosphere, both in a clear sky approximation and in a model containing a representative cloud distribution. The scenarios involved radiative forcing calculations for O3 at normal atmospheric abundance and at a tropospheric abundance depleted by 25 ppbv, at each altitude, for all Northern Hemisphere latitudes. Normal abundances of H2O, CO2, CH4, and N2O were included in the calculations. The IR radiative forcing was calculated using a correlated k-distribution radiative transfer model. The tropospheric radiative forcing values are compared to the IPCC formulae for ozone tropospheric forcing as well as other published values to determine the validity of the correlated k-distribution approach to the radiative forcing calculations. The results for the global average atmosphere show agreement with previous results to the order of 10 percent. We conclude that the O3 forcing is linear in the background abundance and that the radiative forcing for ozone for the globally averaged atmosphere and the latitude averaged radiative forcing in the clear sky approximation are in agreement to within 10 percent. For the case of an atmosphere in which the tropospheric ozone has been depleted by 25 ppbv at all altitudes in the Northern Hemisphere, the mid latitude zone contributes (approximately)50 percent of the forcing, tropic zone contributes (approximately)37 percent of the forcing and the polar zone contributes (approximately)13 percent of the total forcing. LOCATION AND CHARACTERISTICS OF THE RECONNECTION X-LINE DEDUCED FROM LOW-ALTITUDE SATELLITE AND RADAR OBSERVATIONS
M. Lockwood, C. J. Davis, M. F. Smith, T. G. Onsager, and W. F. Denig Jul. 1994 47 p Prepared in cooperation with Rutherford Appleton Lab., Chilton, England; New Hampshire Univ., Durham; and Phillips Lab., Hanscom AFB, MA
(NASA-TM-110114; NAS 1.15:110114; PB95-129805; RAL-94-081) Avail: Issuing Activity (National Technical Information Service (NTIS))

We present an analysis of a cusp ion step observed between two poleward-moving events of enhanced ionospheric electron temperature. From the computed variation of the reconnection rate and the onset times of the associated ionospheric events, the distance between the satellite and the X-line can be estimated, but with a large uncertainty due to that in the determination of the low-energy cut-off of the ion velocity distribution function, f(E). Nevertheless, analysis of the time series f(t) shows the reconnection site to be on the dayside magnetopause, consistent with the pulsating cusp model, and the best estimate of the X-line location is 13 R(E) from the satellite. The ion precipitation is used to reconstruct the field-parallel part of the Cowley-D ion distribution function injected into the open low latitude boundary layer (LLBL) in the vicinity of the X-line. From this the Alfven speed, plasma density, magnetic field, parallel ion temperature, and flow velocity of the magnetosheath near the X-line can be derived. NTIS

THE EFFECT OF REGIONAL-SCALE SOIL-MOISTURE DEFICITS ON MESOSCALE ATMOSPHERIC DYNAMICS THAT INFLUENCE FIRE SEVERITY
J. D. Fast 30 Sep. 1994 143 p
(Contract DE-AC09-89SR-18035)
(DE95-002682; WSRC-TR-94-0468) Avail: CASI HC A07/MF A02

This study employs a three-dimensional, nonhydrostatic mesoscale model to evaluate the effects of horizontally heterogeneous soil moisture and vegetation type on the atmosphere during two periods in which wildland fires occurred. Numerical sensitivity simulations demonstrate that evapotranspiration significantly affects the boundary-layer structure embedded in the synoptic-scale circulations. In regions with sufficiently moist soils, evapotranspiration increases the humidity and modifies the diurnally varying temperature near the surface. Occasionally, changes in the humidity and temperature fields can also be seen a significant distance downwind of the moist soil regions. The perturbations in the temperature fields ultimately affect the wind speed and direction over or at the boundaries of the moist-soil regions, but only at certain times during the simulation period. The higher humidity also increases the cloudiness and changes the precipitation amounts, indicating that soil moisture and vegetation may play an important role in modifying the spatial distribution and intensity of precipitation. A lower atmospheric stability index, that is an indicator of the potential for wildland fire, is also calculated from the model results. This index is also sensitive to the horizontal distribution of soil moisture and vegetation, especially in regions with relatively moist soils. While only two periods are examined in this study, the impact of surface inhomogeneities in soil moisture and vegetation type on the atmosphere is expected to be highly dependent on the particular synoptic conditions and upon the distribution of soil moisture. METALLIC IONS AND ATOMS IN THE UPPER ATMOSPHERE Final Report, 1 Jan. 1992 - 31 Dec. 1993
Jeffrey M. Forbes 28 Feb. 1994 10 p
(Contract F49620-92-J-0092)
(AD-A285229; AFOSR-94-0582TR) Avail: CASI HC A02/MF A01

The main focus of research under AFOSR Grant F49620-920-J-0092 is to investigate the global and local transport of metallic ions in the upper atmosphere, in particular the layering of ionization, through use of comprehensive numerical models which account for realistic meteoric sources, chemical conversions and sinks, and transport by molecular and eddy diffusion, winds and electric fields. The ultimate goal is to better understand the mechanisms producing ionization layers, and ultimately the seasonal, latitudinal, local time, and temporal variations in the occurrences of ionization layers. Plasma layering can affect HF communications by introducing new reflection paths thus complicating the propagating modes, and presumably in extreme cases by producing blanketing effects. In addition, plasma irregularities may also accompany the sharp gradients characterizing the plasma layers. DTIC

ANALYSIS OF MESOSPHERIC WINDS AND WAVES Final Report, 1 Sep. 1993 - 31 Dec. 1993
Kent L. Miller and Robert G. Roper 5 May 1994 42 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract F49620-93-1-0460)
(AD-A279956; AFOSR-94-0340TR) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

During the four months this grant was operative, a paper expanding on the Arecibo Initiative in Dynamics of the Atmosphere (AIDA '89) incoherent scatter/imaging Doppler interferometry (ISR/IDI) radar comparisons, which used revised data from both techniques, was prepared, and has subsequently been submitted and accepted for publication in the Journal of Atmospheric and Terrestrial Physics. In this paper, 'Mesospheric Wind Studies During AIDA Act 1989: Morphology and Comparison of Various Techniques,' by R. S. Turek, K. L. Miller, R. G. Roper and J. W. Brosnahan, all of the measured line of sight velocity profiles for which data was available from both techniques, rather than a few selected profiles as previously analyzed, were subjected to a statistical analysis. This resulted in comparison of over 200 profiles, ten times more than the 20 previously published. After establishing that the sum of the prevailing wind, diurnal and semidiurnal tides deduced from the IDI data represented the statistical mean of the ISR data, we determined the morphology of the prevailing winds and tides over Arecibo during the April and May AIDA campaigns. The results are presented in this report. DTIC

THE NOVAYA ZEMLYA EVENT OF 31 DECEMBER 1992 AND SEISMIC IDENTIFICATION ISSUES: 15TH ANNUAL SEISMIC RESEARCH SYMPOSIUM
10 Sep. 1993 165 p Symposium held in Vail, CO, 8-10 Sep. 1993 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A279847) Avail: CASI HC A08

On December 31, 1992 a small (mb 2.5) event (hereafter '921231') was detected on Novaya Zemlya by the Threshold Monitor (TM) system. The TM system uses data from the on-line array network to continuously monitor seismic amplitude levels for a number of specified experimental target sites, including the Russian nuclear test range on Novaya Zemlya. The method involves continuous beamforming (i.e., time-aligning and summing the traces for each regional array) for the target beam-steering points, to extract parameters of the beams for continuous assessment of the upper magnitude limit of events at the target site that would go undetected by the Scandinavian array network. When events occur that are above the network noise level, they appear as peaks on the TM beams and are thus tagged for detailed off-line analysis. The 921231 event was detected in this way and was identified as an event that might be of particular interest to ARPA. On receipt of the information ARPA decided to use the 921231 event as an example to test the effectiveness of seismic identification tools and systems that are being developed within the nuclear monitoring research community. STATISTICAL PROPERTIES OF GEOLOGIC FRACTALS
C. Loehle 1994 29 p
(Contract W-31-109-eng-38)
(DE94-019272; ANL/ER/PP-79574) Avail: CASI HC A03/MF A01

To use fractal models for geologic data, the statistical properties of fractals need to be clarified. No sampling or estimation theory for fractals currently exists. Several concrete steps in this direction are taken here. First, the information fractal dimension is proposed as a new measure that is relatively robust with respect to sampling error. The information fractal is tested with field data and is shown to be capable of delineating stratified structures and defining the scale of heterogeneity in the data. Comparison to semivariance analysis reveals the superiority of the fractal model for sample data that are nonisotropic and nonstationary. It is argued that approaches using regression to estimate fractal dimensions of spatial patterns are statistically invalid, and alternatives are proposed. Sampling of geologic objects with transects (e.g., wells) is explored. For nonisotropic media, random placement of transects is shown to give an unreliable estimate of pattern. For transects taken perpendicular to a directional pattern (i.e., strata), it is shown that the man of multiple estimates of the multiscale fractal dimensional profile does converge to the true value. Other sampling issues are addressed. DOE

FRACTAL NATURE AND SCALING OF NORMAL FAULTS, RIO GRANDE RIFT, NM: IMPLICATIONS FOR GROWTH AND STRAIN
K. E. Carter 1994 4 p Presented at the Faults Populations Meeting, Edinburgh, United Kingdom, 17-21 Oct. 1994
(Contract W-7405-eng-36)
(DE94-018261; LA-UR-94-2739; CONF-9410196-1) Avail: CASI HC A01/MF A01

In this paper I introduce a suite of Quaternary normal faults from within an active continental rift and characterize the nature of the relationship between fault dimensions. I address the statistical and geological significance of the fractal analysis used in that characterization and discuss the tectonic implications. Specifically, I suggest (1) scaling laws for a previously unanalyzed population of young normal faults in rift environment; (2) implications for fault growth models in this area, in particular, addressing self-similar growth implied from the population; and (3) estimates for the total strain in this part of the basin, considering the contribution of small to unobserved faults. PROJECT WHITEFEATHER

1994 46 p Prepared for Los Alamos National Lab., NM
(Contract W-7405-eng-36)
(DE94-016575; LA-Sub-94-105) Avail: CASI HC A03/MF A01 (US Sales Only)

Four primary tasks have been carried out in this program. Upon request of LANL, the Eloranta paper was reviewed. It was determined that the correlation solution presented was too computationally complex to execute in the allocated 1 second update time. An alternative algorithm approach was under taken using a simulation baseline. A simulation was developed and applied to generate synthetic LIDAR data from randomized aerosol patches drifting with the wind. Algorithms have been designed and implemented in the simulation to reduce the data and apply it to obtain wind estimates. A substantial effort was completed in reverse engineering the EVIEW data format structure of the supplied data. Finally the collected, LIDAR data has been examined to obtain an assessment of the prospects for successful wind estimation. Unfortunately, the data examination has not shown good prospects for a successful outcome. It is recommended that future data be taken with the procedure previously outlined. Hercules believes that if lidar data is collected using this procedure that wind information will be as successful using the collected data as it was in simulation. DOE

ELECTROSTATIC NOISE IN THE PLASMA ENVIRONMENT AROUND THE SHUTTLE

Boris V. Vayner and Dale C. Ferguson Feb. 1995 9 p Presented at the 26th Plasmadynamics and Lasers Conference, San Diego, CA, 19-22 Jun. 1995; sponsored by AIAA
(RTOP 233-01-0E)
(NASA-TM-106856; E-9447; NAS 1.15:106856; AIAA Paper 95-1944)
Avail: CASI HC A02/MF A01

The Langmuir probe flown as part of the Solar Array Module Plasma Interactions Experiment (SAMPIE) package aboard the space shuttle flight STS-62 was used to determine plasma potential fluctuations in the vicinity of the shuttle. The broadband noise was observed at frequencies 250 - 20,000 Hz. Measurements were performed in ram conditions; thus, it seems reasonable to believe that the influence of spacecraft operations on plasma parameters was absolutely negligible. The average spectrum of fluctuations is in agreement with theoretical predictions. The influence on the observed spectra of arcing generated by high negative bias voltages applied to solar cell samples is briefly discussed. Author

Research focused on identification and collection of a suitable database, identification of parametric representation of the time series seismic waveforms, and the training and testing of neural networks for seismic event classification. It was necessary to utilize seismic events that had a high degree of reliability for accurate training of the neural networks. The seismic waveforms were obtained from the Center for Seismic Studies and were organized into smaller databases for training and classification purposes. Unprocessed seismograms were not well suited for presentation to a neural network because of the large number of data points required to represent a seismic event in the time domain. The parametric representation of the seismic events in some cases provided adequate information for accurate event classification, while significantly reducing the minimum size of the neural network. Various networks have achieved classification rates ranging from 88 percent classification of three class problem to 75 percent for the 5 class problem. The results vary dependent on the number of classes and the method of parametric transformations utilized. Multiple tests were performed in order to statistically average the training and classification rates. Test summaries presented and individual test results are given in the appendix. DTIC

ANATOMY OF THE MIDCONTINENT RIFT BENEATH LAKE SUPERIOR

M. D. Thompson, L. D. McGinnis, C. P. Ervin (University of Northern Illinois, De Kalb, IL.), and M. G. Mudrey (Wisconsin Geological and Natural History Survey, Madison, WI.) 1994 41 p
(Contract W-31-109-eng-38)
(DE94-019298; ANL/ES/PP-76517) Avail: CASI HC A03/MF A01

The structure and geometry of the 1.1-b.y.-old Midcontinent Rift system under Lake Superior is interpreted from 20 seismic reflection profiles recorded during the early and mid-1980s. The seismic data reveal that rift basins under Lake Superior are variable in depth and are partially filled with Keweenawan age sediments to depths of 7 km or more and volcanic flows to depths of 36 km. These rift basins form a continuous and sinuous feature that widens in the Allouez Basin and Marquette Basin in the western and central lake and narrows between White Ridge and the Porcupine Mountains. The rift basin bends southeast around the Keweenaw Peninsula, widens to about 100 km as it extends into the eastern half of Lake Superior, and exists the lake with its axis in the vicinity of Au Sable Point in Pictured Rocks National Lake Shore, about 50 km northeast of Munising, Michigan. The axis of the rift may exit the western end of the lake near Chequamegon Bay in Wisconsin. However, lack of data in that area limits interpretation at this time. Prior to late-stage reverse-faulting, a continuous basin of more uniform thickness was present beneath the lake. Crustal extension during rifting of approximately 50 km was followed by plate convergence and crustal shortening of approximately 30 km, with the major component of thrust from the southeast. Crustal shortening occurred after development of rift grabens and their filling with lava flows, but before deposition of the final sag basin sediments. Integration of information obtained from outcrops with data reported here indicates that the Lake Superior section of the rift is associated with as many as three major boundary faults. DOE

COMPUTER PROGRAMS FOR ANALYSIS OF GEOPHYSICAL DATA

Mikhail Rozhkov and Keith Nakanishi Jun. 1994 119 p
(Contract W-7405-eng-48)
(DE95-002472; UCRL-CR-117756) Avail: CASI HC A06/MF A02

This project is oriented toward the application of the mobile seismic array data analysis technique in seismic investigations of the Earth (the noise-array method). The technique falls into the class of emission tomography methods but, in contrast to classic tomography, 3-D images of the microseismic activity of the media are obtained by passive seismic antenna scanning of the half-space, rather than by solution of the inverse Radon's problem. It is reasonable to expect that areas of geothermal activity, active faults, areas of volcanic tremors and hydrocarbon deposits act as sources of intense internal microseismic activity or as effective sources for scattered (secondary) waves. The conventional approaches of seismic investigations of a geological medium include measurements of time-limited determinate signals from artificial or natural sources. However, the continuous seismic oscillations, like endogenous microseisms, coda and scattering waves, can give very important information about the structure of the Earth. The presence of microseismic sources or inhomogeneities within the Earth results in the appearance of coherent seismic components in a stochastic wave field recorded on the surface by a seismic array. By careful processing of seismic array data, these coherent components can be used to develop a 3-D model of the microseismic activity of the media or images of the noisy objects. Thus, in contrast to classic seismology where narrow windows are used to get the best time resolution of seismic signals, our model requires long record length for the best spatial resolution. DOE

RARE GASES SYSTEMATICS AND MANTLE STRUCTURE Abstract Only
C. J. Allegre and T. Staudacher *In* Lunar and Planetary Inst., Conference on Deep Earth and Planetary Volatiles 1994 p 1 Prepared in cooperation with Paris VII Univ., France (For primary document see N95-21777 06-46)
Avail: CASI HC A01/MF A01

The following points are emphasized: one of the most important ones is certainly the first set of experimental data on the solubility of noble gases in metal phases at intermediate pressures, since the core was certainly not formed at ultra high pressures, as emphasized by Ahrens and confirmed by trace elements systematics Wanke. The experimental data clearly show that the core can not be a major reservoir for terrestrial rare gases; the second point is a more elaborate reconsideration of the (40)K-(40)Ar budget of the Earth. This shows that (40)Ar contained in continental crust plus upper mantle plus atmosphere is at maximum half of the (40)Ar inventory of the whole earth. This implies the existence of a two layered mantle; the third point is the discovery by the Australian noble gases group of the existence of high (20)Ne/(22)Ne and low (21)Ne/(22)Ne isotopic ratios in Loihi seamount samples. This results which are different to the MORB ratios confirm the idea of a two layered model, but suggest the existence of a primordial solar type Ne reservoir. Several possibilities about the origin of this (20)Ne excess in the mantle will be discussed; The high (40)Ar/(36)Ar, (129)Xe/(130)Xe and (134) Xe/(130)Xe, (136)Xe/(130)Xe are confirmed by new data. The corresponding ratios for the lower mantle will be discussed. (40)Ar/(36)Ar ratios up to 6000 can be accepted and will not modify the general model of the mantle. They confirm the atmosphere chronology, about 85 percent of the atmosphere was formed in the first 50 My and 15 percent later on. Author

VOLATILES IN THE EARTH: ALL SHALLOW AND ALL RECYCLED Abstract Only
Don L. Anderson *In* Lunar and Planetary Inst., Conference on Deep Earth and Planetary Volatiles 1994 p 2 (For primary document see N95-21777 06-46)
Avail: CASI HC A01/MF A01

A case can be made that accretion of the Earth was a high-temperature process and that the primordial Earth was dry. A radial zone-refining process during accretion may have excluded low-melting point and volatile material, including large-ion lithophile elements toward the surface, leaving a refractory and zoned interior. Water, sediments and altered hydrous oceanic crust are introduced back into the interior by subduction, a process that may be more efficient today than in the past. Seismic tomography strongly suggests that a large part of the uppermantle is above the solidus, and this implies wet melting. The mantle beneath Archean cratons has very fast seismic velocities and appears to be strong to 150 km or greater. This is consistent with very dry mantle. It is argued that recycling of substantial quantities of water occurs in the shallow mantle but only minor amounts recycle to depths greater than 200 km. Recycling also oxidizes that mantle; ocean island ('hotspot') basalts are intermediate in oxidation state to island-arc and midocean ridge basalts (MORB). This suggests a deep uncontaminated reservoir for MORB. Plate tectonics on a dry Earth is discussed in order to focus attention on inconsistencies in current geochemical models of terrestrial evolution and recycling. Author

IMPACT DEGASSING OF WATER AND NOBLE GASES FROM SILICATES Abstract Only
S. Azuma, H. Hiyagon, Y. Iijima (Nagoya Univ., Aichi, Japan.), and Y. Syono (Tohoku Univ., Sendai, Japan.) *In* Lunar and Planetary Inst., Conference on Deep Earth and Planetary Volatiles 1994 p 3 (For primary document see N95-21777 06-46)
Avail: CASI HC A01/MF A01

Previous shock experiments by Ahrens and his colleagues show that degassing of H2O and CO2 occurs at 8-65GPa from hydrous minerals such as serpentine. In early solar system, the impact degassing would have played an important part in the formation of primary-atmospheres of the terrestrial planets. However, degassing conditions of noble gases are not well-known because there are few experiments for them. We conducted some shock recovery experiments to investigate the degassing condition and to understand the degassing mechanisms of water and noble gases. We used natural richterites (Ri), amphibolites (Am), serpentines (Sep) and orthoclases (or) as target samples. These, except Sep, contain radiogenic noble gases such as (40)Ar. The samples were put in stainless steel containers, and were show by a rail gun at ISAS or single-stage powder guns at Nagoya or Tohoku University, Japan. We used two kinds of containers: 'open' type containers having a ventilating path for released volatiles for most of samples and 'closed' type ones for some samples for comparison. On Ri and Sep, we made shock experiments for pre-heated (at 400-500 C) and unheated targets, and for powdered and uncrushed samples. Water and noble gases were analyzed both for the recovered shocked samples and the unshocked original samples, and the fractions of the degassed volatiles were calculated by comparing them. Water content in the sample was analyzed by thermo-gravimetry. Noble gases were extracted by heating the samples under high vacuum and analyzed with a sector-type mass spectrometer. Author

D/H RATIOS AND H2O CONTENTS OF MANTLE-DERIVED AMPHIBOLE MEGACRYSTS FROM DISH HILL, CALIFORNIA Abstract Only
David R. Bell and T. C. Hoering *In* Lunar and Planetary Inst., Conference on Deep Earth and Planetary Volatiles 1994 p 4 (For primary document see N95-21777 06-46)
Avail: CASI HC A01/MF A01

D/H ratios are, in principle, useful in characterizing reservoirs of mantle hydrogen and as tracers of volatile transfer processes in Earth's interior. In practice, however, interpretation of isotopic measurements on mantle derived H is complicated by surface processes such as contamination and degassing which may alter the primary D/H ratio. Although there are indications that water associated with subduction zones and certain chemically enriched basalts is enriched in D relative to 'typical' upper mantle water, the extent of isotopic heterogeneity of mantle H remains uncertain. Kaersutitic amphibole megacrysts in alkaline basalts are one of the most widespread sources of mantle water and are therefore potentially useful for large-scale regional studies of D/H variation. However, D/H ratios of these amphiboles vary widely (from plus 8 to minus 113 percent), even in samples from the same locality, so that this potential has yet to be realized. In order to investigate the origin of this variability, and to explore the possibility that primary mantle D/H ratios may be deduced from these amphiboles, we analyzed the D/H ratios and chemical compositions of a suite of 17 kaersutitic amphiboles from Dish Hill, California. This work contrasts with previous studies in which sampling is widespread, but representatives from any given locality are few. Samples were collected from a restricted area on the southern flank of the volcanic center and are associated with the basal volcanic breccia. Fourteen of the samples were large single crystals or crystal fragments (megacrysts, 0.4 to 30 grams), believed to derive from pegmatitic veins crystallized from melts in the mantle. Two were coarse-grained intergrowths of amphibole with olivine and spinel, and one was a thin (2 mm) selvage on a peridotite xenolith. Author

THERMOCHEMISTRY OF DENSE HYDROUS MAGNESIUM SILICATES Abstract Only

Kunal Bose, Pamela Burnley (Colorado Univ., Boulder, CO.), and Alexandra Navrotsky *In* Lunar and Planetary Inst., Conference on Deep Earth and Planetary Volatiles 1994 p 5 (For primary document see N95-21777 06-46)
Avail: CASI HC A01/MF A01

Recent experimental investigations under mantle conditions have identified a suite of dense hydrous magnesium silicate (DHMS) phases that could be conduits to transport water to at least the 660 km discontinuity via mature, relatively cold, subducting slabs. Water released from successive dehydration of these phases during subduction could be responsible for deep focus earthquakes, mantle metasomatism and a host of other physico-chemical processes central to our understanding of the earth's deep interior. In order to construct a thermodynamic data base that can delineate and predict the stability ranges for DHMS phases, reliable thermochemical and thermophysical data are required. One of the major obstacles in calorimetric studies of phases synthesized under high pressure conditions has been limitation due to the small (less than 5 mg) sample mass. Our refinement of calorimeter techniques now allow precise determination of enthalpies of solution of less than 5 mg samples of hydrous magnesium silicates. For example, high temperature solution calorimetry of natural talc (Mg(0.99) Fe(0.01)Si4O10(OH)2), periclase (MgO) and quartz (SiO2) yield enthalpies of drop solution at 1044 K to be 592.2 (2.2), 52.01 (0.12) and 45.76 (0.4) kJ/mol respectively. The corresponding enthalpy of formation from oxides at 298 K for talc is minus 5908.2 kJ/mol agreeing within 0.1 percent to literature values. Author

MODELING THE EFFECT OF WATER ON MANTLE RHEOLOGY Abstract Only

Ch. Bounama and S. Franck *In* Lunar and Planetary Inst., Conference on Deep Earth and Planetary Volatiles 1994 p 6 (For primary document see N95-21777 06-46)
Avail: CASI HC A01/MF A01

To study the thermal history of the Earth we use a parameterized model of mantle convection. This model includes a mathematical description of de- and regassing processes of water from the Earth's mantle. The rates of this processes are considered to be directly proportional to the seafloor spreading rate. The kinematic viscosity of the mantle depends on the temperature/pressure as well as on the volatile content. Dissolved volatiles such as water weaken the minerals by reducing their activation energy for solid state creep. Karato and Toriumi showed a power law dependence between creep rate and water fugacity derived from experimental results. Therefore, we use such flow parameters of diffusion creep in olivine under wet and dry conditions to calculate the mantle viscosity as a function of the water content. Because the creep rate is proportional to the concentration of water-related point deflects we assume that the water fugacity is proportional to the water weight fraction. An equation for the steady-state strain rate under wet conditions is established. To assess the unknown constant K in this equation, we use flow law parameters given by Karato and Wu as well as the results of McGovern and Schubert. Author

NOBLE GAS ISOTOPES AND HALOGENS IN VOLATILE-RICH INCLUSIONS IN DIAMONDS Abstract Only

Raymond Burgess and Grenville Turner *In* Lunar and Planetary Inst., Conference on Deep Earth and Planetary Volatiles 1994 p 7 (For primary document see N95-21777 06-46)
Avail: CASI HC A01/MF A01

Application of the (40)Ar-(39)Ar method and noble gas studies to diamonds has increased our understanding of their age relationships to the host kimberlite or lamproite, and of the source and composition of volatile-rich fluids in the upper mantle. The properties of diamond (inert, high mechanical strength and low gas diffusivities) means they are especially useful samples for studying gases trapped deep within the earth (less than 150 km) as they are unlikely to have undergone loss or exchange of entrapped material since formation. Volatile-rich fluids (H2O-CO2) are important agents for metasomatic processes in the upper mantle, and the noble gases and halogens preferentially partition into this phase leading to a strong geochemical coherence between these groups of elements. The abundances of the halogens in the major reservoirs of the Earth shows a marked progression from chlorine, concentrated in the oceans, through to iodine which, through its affinity to organic material, is concentrated mainly in sediments. Abundances in the upper mantle are low. This is particularly true for iodine which is of special interest in view of its potential significance as an indicator of sediment recycling and by way of its link to (129)Xe amomalies in the mantle through the low extinct isotope (129)I. Extensions of the (40)Ar-(39)Ar technique enable measurements of halogens and other elements (K, Ca, Ba, U) by production of noble gas isotopes from these species during neutron irradiation. Samples analyzed in this way include 15 coated stones from an unknown source in Zaire, 3 boarts from the Jwaneng and 1 boart from the Orapa kimberlites, both in Botswana. Author

ORIGIN AND LOSS OF THE VOLATILES OF THE TERRESTRIAL PLANETS Abstract Only c91

T. M. Donahue *In* Lunar and Planetary Inst., Conference on Deep Earth and Planetary Volatiles 1994 p 8 (For primary document see N95-21777 06-46)
Avail: CASI HC A01/MF A01

How the terrestrial planets obtained their original endorsement of volatiles and proceeded to lose them selectively is the theme of this paper. Where good and convincing answers to these questions are still not available, the principal issues are becoming better and better understood, and thus many of the decisive measurements and calculations needed to obtain them can be well defined. In this paper our present inventories of volatiles such as the noble gases, hydrogen compounds and atmophiles such as CO2, N2, and O2 will be presented. Careful attention will be given to isotopic ratios and their significance. Escape processes past and present - blow off impact erosion, thermal and non-thermal loss of neutral and ionic species will be discussed, and the contribution of each to volatile loss assessed. It will be argued that our understanding of these processes is adequate to explain the present level of fractionation of many of the noble gases and their isotopes on all the terrestrial planets. It will also be argued that we are close to understanding loss of hydrogen well enough to assess reasonably the early abundance of water on early Venus and Mars. Author

STRUCTURE AND STABILITY OF HYDROUS MINERALS AT HIGH PRESSURE Abstract Only

T. S. Duffy, Y. Fei, C. Meade, R. J. Hemley, and H. K. Mao *In* Lunar and Planetary Inst., Conference on Deep Earth and Planetary Volatiles 1994 p 9 (For primary document see N95-21777 06-46)
Avail: CASI HC A01/MF A01

The presence of even small amounts of hydrogen in the Earth's deep interior may have profound effects on mantle melting, rheology, and electrical conductivity. The recent discovery of a large class of high-pressure H-bearing silicates further underscores the potentially important role for hydrous minerals in the Earth's mantle. Hydrogen may also be a significant component of the Earth's core, as has been recently documented by studies of iron hydride at high pressure. In this study, we explore the role of H in crystal structures at high pressure through detailed Raman spectroscopic and x ray diffraction studies of hydrous minerals compressed in diamond anvil cells. Brucite, Mg(OH)2, has a simple structure and serves as an analogue for the more complex hydrous silicates. Over the past five years, this material has been studied at high pressure using shock-compression, powder x ray diffraction, infrared spectroscopy, Raman spectroscopy, and neutron diffraction. In addition, we have recently carried out single-crystal synchrotron x-ray diffraction on Mg(OH)2 and Raman spectroscopy on Mg(OD)2 at elevated pressure. From all these studies, an interesting picture of the crystal chemical behavior of this material at high pressure is beginning to emerge. Some of the primary conclusions are as follows. First, hydrogen bonding is enhanced by the application of pressure. Second, layered minerals which are elastically anisotropic at low pressure may not be so at high pressure. Furthermore, the brucite data place constraints on the effect of hydrogen on seismic velocities and density at very high pressure. Third, the stability of hydrous minerals may be enhanced at high P by subtle structural rearrangements that are difficult to detect using traditional probes and require detailed spectroscopic analyses. Finally, brucite appears to be unique in that it undergoes pressure-induced disordering that is confined solely to the H-containing layers of the structure. Author

RECYCLING OF VOLATILES AT SUBDUCTION ZONES: NOBLE GAS EVIDENCE FROM THE TABAR-LIHIR-TANGA-FENI ARC OF PAPUA NEW GUINEA Abstract Only

Kenneth Farley, Brent McInnes, and Desmond Patterson *In* Lunar and Planetary Inst., Conference on Deep Earth and Planetary Volatiles 1994 p 10 (For primary document see N95-21777 06-46)

Avail: CASI HC A01/MF A01

Convergent margin processes play an important but poorly understood role in the distribution of terrestrial volatile species. For example, subduction processes filter volatiles from the subducting package, thereby restricting their return to the mantle. In addition, once extracted from the downgoing slab, volatiles become an essential component in the petrogenesis of island arc magmas. The noble gases, with their systematic variation in physical properties and diversity of radiogenic isotopes, should carry a uniquely valuable record of these processes. However, thus far studies of noble gases in arc volcanics have achieved only limited success in this regard. Subduction-related lavas and geothermal fluids carry (3)He/(4)He ratios equal to or slightly lower than those found in the depleted upper mantle source of mid-ocean ridge basalts. Apparently slab-derived helium (which should have (3)He/(4)He much less than MORB) is extensively diluted by MORB-like helium from the mantle wedge, making it difficult to use helium as a tracer of convergent margin processes. Interpretation of the heavier noble gases (Ne-Ar-Kr-Xe) in arc lavas has also proven difficult, because the lavas carry low noble gas concentrations and hence are subject to pervasive atmospheric contamination. The low noble gas concentrations may be a consequence of degassing in the high level magma chambers characteristic of arc stratovolcanos. We have recently initiated a project to better constrain the behavior of volatiles in subduction zones through geochemical studies of the tectonically unusual volcanoes of the Tabar-Lihir-Tanga-Feni (TLTF) arc in the Bismarck Archipelago, Papua New Guinea. MANTLE DEVOLATILIZATION AND RHEOLOGY IN THE FRAMEWORK OF PLANETARY EVOLUTION Abstract Only c91

S. Franck and Ch. Bounama *In* Lunar and Planetary Inst., Conference on Deep Earth and Planetary Volatiles 1994 p 11 (For primary document see N95-21777 06-46)

Avail: CASI HC A01/MF A01

We investigate the thermal history of an Earth-like planet with the help of a parameterized mantle convection model including the volatile exchange between mantle and surface reservoirs. The weakening of mantle silicates by dissolved volatiles is described by a functional relationship between creep rate and water fugacity. We use flow law parameters of diffusion creep in olivine under dry and wet conditions. The mantle degassing rate is considered as directly proportional to the seafloor spreading rate, which is also dependent on the mantle heat flow. To calculate the spreading rate, we assume that the heat flow under the mid-ocean ridges is double the average mantle heat flow. The rate of regassing also depends on the seafloor spreading rate as well as on other factors like the efficiency of volatile recycling through island arc volcanism. Both mechanisms (de- and regassing) are coupled self-consistently with the help of the parameterized convection model under implementation of a temperature and volatile-content-dependent mantle viscosity. SPATIAL VARIATION OF PRIMORDIAL 3-He IN CRUSTAL FLUIDS ALONG THE EAST-AFRICAN RIFT SYSTEM (THE ETHIOPIAN AND THE KENYA RIFT SECTION) Abstract Only

E. Griesshaber, S. Weise, and G. Darling (Geological Survey of Britain, Wallingford, England.) *In* Lunar and Planetary Inst., Conference on Deep Earth and Planetary Volatiles 1994 p 12 (For primary document see N95-21777 06-46)

Avail: CASI HC A01/MF A01

(3)He/(4)He compositions are presented for groundwater samples from the Ethiopian segment of the East-Afrikan Rift and from its northern extension, the adjacent Afar region (Djibuti). Helium isotope data are compared to those obtained previously from the Gregory Rift, south of Ethiopia. The distribution pattern of mantle-derived volatiles along the entire East-African-Rift (-from south Kenya to Djibuti-) is discussed and their sources are identified. Helium isotope ratios (R) for samples from the Ethiopian part of the Rift range from 6.3 to 16.0 times the atmospheric ratio (Ra=1.4 x 10(exp -6) and thus show together with a MOR component a considerable hotspot helium component. These mantle helium concentrations are comparable to those observed in groundwaters and volcanic rocks from the Afar plume region in Djibuti. Here R/Ra values range from 9 to 13 times the atmospheric composition, with mantle-derived helium concentrations being higher than at spreading ocean ridges. R/Ra values from Ethiopia and Djibuti are entirely different from those observed in groundwaters at the southerly extending Gregory Rift in Kenya, where R/Ra values scatter between 0.5 and 6. At the northernmost part of the Gregory Rift, close to Ethiopia mantle helium contents are slightly higher, with R/Ra-values varying between 6.5 and 8.0. Author

TRANSPORTATION OF VOLATILE ELEMENTS IN THERMALLY EVOLVING PLANETESIMALS: AN IMPORTANT ROLE OF METALLIC IRON Abstract Only c90

K. Hashizume and N. Sugiura (Tokyo Univ., Japan.) *In* Lunar and Planetary Inst., Conference on Deep Earth and Planetary Volatiles 1994 p 13 (For primary document see N95-21777 06-46)

Avail: CASI HC A01/MF A01

Ordinary chondrites are considered to have experienced thermal metamorphism in small bodies. We are interested in behaviors of volatile elements in such a kind of thermally evolving planetesimals. Volatile elements generally have high vapor pressures at high temperature. In porous bodies, with a high gas permeability, volatile elements are transported efficiently over a long range. Behavior of volatile elements transported by permeable gas flow can be handled by an equation whose form is similar to that of the equation of thermal diffusion. We can follow transportation of heats and volatile elements in planetesimals, when parameters in these equations, initial conditions and chemical behavior of volatile elements are given. Recently, we discovered that nitrogen in equilibrated H-chondrites is mainly trapped in taenite (f.c.c. Fe-Ni), probably dissolved in interstitial sites. Fegley suggests that metallic iron cannot trap nitrogen in the solar nebula gas due to its very low nitrogen partial pressure. Approximately 1 bar of nitrogen pressure is required to explain the nitrogen content in taenite. We may expect high nitrogen gas partial pressure (possibly produced by vaporization of nitrogen-bearing solids such as organic materials) at the interior of thermally evolving planetesimals. Kinetic behavior of nitrogen in taenite suggests that it can easily be equilibrated with the ambient nitrogen gas at temperatures of approximately 500 C or higher. We consider that nitrogen is trapped in taenite through a nitrogen redistribution process occurred during the thermal metamorphic event. Author

HYDROGEN AND RELATED MATERIALS AT HIGH DENSITY: PHYSICS, CHEMISTRY AND PLANETARY IMPLICATIONS Abstract Only

R. J. Hemley, H. K. Mao, T. S. Duffy, A. Goncharov, W. Vos, C. S. Zha, J. H. Eggert, M. Li, and M. Hanfland *In* Lunar and Planetary Inst., Conference on Deep Earth and Planetary Volatiles 1994 p 14 (For primary document see N95-21777 06-46)

Avail: CASI HC A01/MF A01

Recent studies of low-Z molecular materials including hydrogen to multimegabar pressures (less than 300 GPa) have uncovered a range of phenomena relevant to understanding the nature of the interiors of the outer planets and their satellites. Synchrotron x ray diffraction measurements (to 42 GPa) have been used to determine the crystal structure of the solid (hexagonal-close packed) and equation of state. Sound velocities in fluid and solid hydrogen (to 24 GPa) have been inverted to obtain elastic constants and aggregate bulk and shear moduli. In addition, an improved intermolecular potential has been determined which fits both static and shock-wave data. Use of the new potential for the molecular envelope of Jupiter suggests the need for major revisions of existing Jovian models or a reanalysis of reported free oscillations for the planet. Studies at higher pressures (greater than 100 GPa) reveal a sequence of pressure-induced symmetry-breaking transitions in molecular hydrogen, giving rise to three high-pressure phases (1, 2, and 3). Phase 1 is the rotationally disordered hcp phase which persists from low pressure to well above 100 GPa at high temperature (e.g., 300 K). Phase 2 is a low-temperature, high-pressure phase (transition at 100 GPa and 77 K in H2) with spectral features indicative of partial rotational ordering and crystallographic distortion. The transition to Phase 3 at 150 GPa is accompanied by a weakening of the molecular bond, gradual changes in orientational ordering, strong enhancement of the infrared intramolecular vibrational absorption, and strong intermolecular interactions similar to those of ambient-pressure network solids. Studies of the phase diagram reveal a triple point near 130 K and 160 GPa. Higher pressure measurements of vibrational spectra place a lower bound of approximately 250 GPa on the predicted transition pressure for dissociation of molecular hydrogen to form a monatomic metal. LOSS OF SOLAR He AND Ne FROM IDPS IN SUBDUCTING SEDIMENT: DIFFUSION AND THE EFFECT OF PHASE CHANGES Abstract Only

H. Hiyagon *In* Lunar and Planetary Inst., Conference on Deep Earth and Planetary Volatiles 1994 p 15 (For primary document see N95-21777 06-46)

Avail: CASI HC A01/MF A01

The results of the diffusion experiment for solar He and Ne in IDP's in a magnetic separate from Pacific Ocean sediment suggest that solar He and Ne would be easily released from IDP grains and hence lost from subducting slabs at shallow depths. However, since the diffusion experiments was conducted under high vacuum, there may be a possibility that magnetite grains, which are supposedly the main constituent of the magnetic fraction, might be partly reduced to form a metal phase due to low oxygen fugacity in the experimental condition. If this is the case, such a phase change might affect the gas release and hence the results of the diffusion coefficients. In order to examine whether or not such a phase change really occurred in the condition of the diffusion experiment, I conducted a heating experiment for a magnetic separate from Pacific Ocean sediment. In the same condition as in the diffusion experiment, and the run products were examined with an x ray diffraction method. Three samples were prepared: they were wrapped with platinum foil, put in a vacuum line, and heated in a molybdenum crucible for two hours at 500 C, 800 C,and 950 C, respectively. After cooling the furnace, the samples were taken out from the crucible and analyzed with an x ray diffraction method. Author

SOLAR HELIUM AND NEON IN THE EARTH Abstract Only

M. Honda, I. McDougall, and D. B. Patterson (California Inst. of Tech., Pasadena, CA.) *In* Lunar and Planetary Inst., Conference on Deep Earth and Planetary Volatiles 1994 p 16 (For primary document see N95-21777 06-46)

Avail: CASI HC A01/MF A01

Neon isotopic compositions in mantle-derived samples commonly are enriched in (20)Ne and (21)Ne relative to (22)Ne compared with atmospheric neon ((20)Ne/(22)Ne and (21)Ne/(22)Ne ratios in atmospheric neon are 9.8 and 0.029, respectively), together with significant primordial (3)He. Such results have been obtained on MORB's, intraplate plume-related oceanic island basalts, backarc basin basalts, mantle xenoliths, ancient diamonds and CO2 well gases (e.g., 1 - 8). The highest (20)Ne/(22)Ne ratio observed in MORB glasses (= 13.6 plus or minus 1.3 is close to the solar value (= 13.6, as observed in solar wind). In order to explain the enrichment of (20)Ne and (21)Ne relative to atmospheric neon for samples derived from the mantle, it is necessary to postulate the presence of at least two distinct non-atmospheric components. The two most likely candidates are solar and nucleogenic ((20)Ne/(22)Ne solar = 13.6 (21)Ne/(22)Ne solar = 0.032, (20)Ne/(22)Ne nucleogenic = 2.5 and (21)Ne/(22)Ne nucleogenic = 32). This is because solar neon is the only known component with a (20)Ne/(22)Ne ratio greater than both the atmospheric value and that observed in samples derived from the mantle. Nucleogenic neon is well known to elevate (21)Ne/(22)Ne ratios. Neon isotopic signatures observed in mantle-derived samples can be accounted for by mixing of the three neon end members: solar, nucleogenic and atmospheric. Author

ATMOSPHERES OF THE MOON AND MERCURY Abstract Only c91

D. M. Hunten *In* Lunar and Planetary Inst., Conference on Deep Earth and Planetary Volatiles 1994 p 17 (For primary document see N95-21777 06-46)

Avail: CASI HC A01/MF A01

Mercury and the Moon have long been considered to be similar objects, but this view was based on limited information at visible wavelengths. It is now known that real differences exist in the atmospheres and in the rock types as deduced from mid-infrared observations. Lunar Ar and perhaps Ne were observed from Apollo landed experiments in spite of a large local background. An ultraviolet spectrometer (UVS) in orbit placed upper limits on a number of gases including H and O. At Mercury, the UVS on Mariner 10 measured H, He, and perhaps O and again a number of upper limits for other gases. Less than a decade ago, emissions of Na and K were observed from the ground, with abundances 2 orders of magnitude smaller on the Moon than on Mercury. It is likely that impacting meteoroids bring a significant amount of water to Mercury, whose atmosphere should therefore contain water vapor. This notion is supported by the recent discovery of radar-bright polar deposits almost certainly composed of ice. A variety of origins is likely for the different components. Impact of meteoroids could supply water, Na, and K, and could also vaporize surface material; Na, K, and Ar could be degassed from the crust. H is probably from the solar wind, and He could reasonably come from degassing or the solar wind. A substantial loss process for all components is photoionization (or dissociation); ions on one side are swept away into the solar wind and on the other are swept back to the surface. This process is complicated at Mercury by its permanent magnetic field, but there is little doubt that both loss and recycling still occur. Some of the recycling probably occurs by way of the magnetotail through night side auroral precipitation; atoms implanted in the surface will diffuse back into the atmosphere shortly after dawn, an effect that seems to be present for K. Finally the light atoms H and He have high enough velocities to escape directly, an effect that may be enhanced by the suprathermal velocity distributions that are likely to be present. Author

PRIMITIVE Xe IN THE ATMOSPHERES OF EARTH AND MARS Abstract Only

G. Igarashi *In* Lunar and Planetary Inst., Conference on Deep Earth and Planetary Volatiles 1994 p 18 (For primary document see N95-21777 06-46)

Avail: CASI HC A01/MF A01

Published data on Xe isotope compositions in primitive carbonaceous meteorites are examined using multidimensional correlation analysis. Distribution of the Xe data in multidimensional data space, except for (129)Xe, can be characterized by a single component, whose isotope composition is identical to 'H plus L minus Xe'. Additional small contributions to the data variations, less than 1 percent of total variations, can be attributed to 'S minus Xe' as well as atmospheric contamination. Isotopic composition of primitive Xe common to the Earth's atmosphere and carbonaceous meteorites are determined with the same assumption as adopted by Pepin and Phinney: primitive Xe is precisely related to fission-free Xe in the Earth's atmosphere by mass fractionation. The determined isotopic composition of primitive Xe is closer to Solar-type Xe, rather than U-Xe (and the primitive Xe estimated from chondrite-achondrite correlation. Hence, the present published data on Xe isotope compositions in meteorites do not seem to require any special component for the primitive Xe common to the Earth's atmosphere and carbonaceous meteorites. Thus Earth's accreting planetesimals would have trapped Xe from the surrounding nebula gases where Xe isotope composition is identical to Solar-type Xe. The trapped Xe was subsequently subject to isotopic fractionation due to gravitational separation as planetesimals grew. Finally fissiogenic Xe from (244)Pu was added to form the present Xe isotope composition of the Earth's atmosphere. The amount of fissiogenic (136)Xe is estimated to be 2.6 percent of the total amount of (136)Xe in the atmosphere, which is about a half of that estimated by Pepin and Phinney (4.65 percent). Author

MARS ATMOSPHERIC LOSS AND ISOTOPIC FRACTIONATION BY PICK-UP-ION SPUTTERING AND PHOTOCHEMICAL ESCAPE Abstract Only **c91**
B. M. Jakosky, R. O. Pepin (Minnesota Univ., Minneapolis, MN.), R. E. Johnson (Virginia Univ., Charlottesville, VA.), and J. L. Fox (State Univ. of New York, Stony Brook, NY.) *In* Lunar and Planetary Inst., Conference on Deep Earth and Planetary Volatiles 1994 p 19 (For primary document see N95-21777 06-46)
Avail: CASI HC A01/MF A01

We examine the effects of loss of constituents of the Martian atmosphere due to sputtering by solar-wind pick-up ions and photochemical escape during the last 3.8 billion years. Sputtering is capable of efficiently removing species from the upper atmosphere to space, including the light noble gases; nitrogen and oxygen are removed by both sputtering ad photochemical processes. Due to diffusive separation (by mass) above the homopause, removal from the top of the atmosphere will fractionate the isotopes of each species, with the lighter isotope being preferentially lost. This allows current measurements of the isotopic ratios to be used as a measure of the atmospheric evolution as integrated over geologic time. For carbon and oxygen, isotopic fractionation is buffered by exchange of atmospheric species with non-atmospheric reservoirs of CO2 and H2O. This allows us to determine the size of the non-atmospheric reservoirs which are capable of mixing with the atmosphere; these reservoirs can be CO2 absorbed in the regolith and/or H2O in the polar ice caps. Such an exchangeable reservoir is required in order to keep the fractionation of the atmospheric gases as low as is observed. Author

THE PRIMARY CARBON AND THE FORMATION OF CARBON SPECIES IN TERRESTRIAL MAGMAS Abstract Only
A. Kadik and V. I. Vernadsky *In* Lunar and Planetary Inst., Conference on Deep Earth and Planetary Volatiles 1994 p 20 (For primary document see N95-21777 06-46)
Avail: CASI HC A01/MF A01

There is general agreement that primary carbon and redox state of mantle play an important role in the formation of carbon species in the terrestrial basalts as well as in the composition of gases, evacuated by these liquids to the upper layers of the Earth. It is expected, that interaction between native carbon and production of partial melting of the upper mantle : C(graphite,diamond) + O2(-) (melt) + O2 = CO3(2-) (melt) (1) leads to the formation of CO3(2-) (carbonate ion) in melt. Next mechanism, that may control the presence of free carbon and the formation of C-bearing components in magmas, is the carbon solubility in minerals under mantle conditions by participating in point defect equilibria. DYNAMICS OF VOLATILE DELIVERY FROM OUTER TO INNER SOLAR SYSTEM Abstract Only **c90**
W. M. Kaula *In* Lunar and Planetary Inst., Conference on Deep Earth and Planetary Volatiles 1994 p 21 (For primary document see N95-21777 06-46)
Avail: CASI HC A01/MF A01

Owen et al. propose that the Ar excess of Venus compared to Earth was caused by impact of a large icy planetesimal from the outer solar system, where temperatures were low enough for Ar to adhere to ice, about 30 K. A body of solar Ar/Si and C/H similar to Pluto and Triton less than 100 km diameter would suffice. However, direct delivery from the Uranus-Neptune zone to Venus would result in a very high approach velocity, causing erosion rather than accretion of volatiles. It would also be an extremely improbable event. Virtually all icy bodies scattered from the Uranus-Neptune zone to the terrestrial zone were strongly perturbed by Jupiter, but even then arrived at Venus (or Earth) at too-high velocities. What is needed is a 'deboost' of bodies scattered inward from Jupiter by Earth and Venus perturbations, prior to impact into Venus. This has low probability, since the influence radii of Venus and Earth for the high velocities are small compared to that of Jupiter for the lower velocities further out. It is desirable that this problem be examined by an integrator that allows for close approaches, such as developed by Levison and Duncan. However, it would be a long and expensive computation compared to explaining short-period comets to accomplish the third 'deboost' phase. But since close encounters dominate in such distant scattering, an Opik algorithm seems the appropriate reconnaissance tool. Author

PHASE E IN A WATER-SATURATED PERIDOTITE SYSTEM AT 9.3 GPa Abstract Only
Tatsuhiko Kawamoto, Kurt Leinenweber, and Richard L. Hervig *In* Lunar and Planetary Inst., Conference on Deep Earth and Planetary Volatiles 1994 p 22 (For primary document see N95-21777 06-46)
Avail: CASI HC A01/MF A01

The stability of hydrous phases in a natural upper mantle system has been investigated at 9.3 GPa using a gel of KLB-1 peridotite composition with brucite which contains 14 wt. percent (30 atom. percent) water. No hydrous mineral was found at 950 (+150 -50) degree C. At 800 degree C, an assemblage of phase A, phase E, enstatite, clinohumite, and garnet is obtained. Although there is a significant thermal gradient over the sample, phase E is found to be surrounded by phase A in the lower temperature part. Electron probe analyses show that phase E has 35.5 SiO2, 4.4 Al2O3, 41.1 MgO and 8.5 wt. percent FeO* (Mg value is 90) with an oxide sum of 89.7 wt. percent, and possesses a stoichiometry similar to that proposed by Kanzaki. CaO and TiO2 are both less than 0.1 wt. percent. Coexisting phase A has 0.5 wt. percent CaO but only 0.4 wt. percent Al2O3 concentration. Phase A coexists with only enstatite in the water-saturated MgO-FeO-SiO2 system at 800 degree C and 9.3 GPa as well as the results in the water-saturated MgO-SiO2 system. Therefore it is suggested that the addition of Al2O3 expands the stability field of phase E to lower than 13 - 17 GPa in the water-saturated MgO-SiO2 system. Author

NITROGEN ISOTOPIC COMPONENTS IN THE EARLY SOLAR SYSTEM Abstract Only **c90**
J. F. Kerridge *In* Lunar and Planetary Inst., Conference on Deep Earth and Planetary Volatiles 1994 p 23-24 (For primary document see N95-21777 06-46)
Avail: CASI HC A01/MF A01

It is quite common to take the terrestrial atmospheric value of (15)N/(14)N (0.00366) as typical of nitrogen in the early solar system, but in fact there is little reason to suppose that this value had a nebula-wide significance. Indeed, it is not clear that there was a unique solar-system-wide (15)N/(14)N ratio, of whatever value. Here we review what is known about the distribution of the nitrogen isotopes among those solar-system objects that have been sampled so far and conclude that those isotopes reveal widespread inhomogeneity in the early solar system. Whether the isotopically distinct primordial components implied by this analysis were solid or gaseous or a mixture of both is not known. The isotopic composition of N in the Earth's mantle is controversial: estimates range from a 1.1 percent depletion in (15)N to a 1.4 percent enrichment. (Isotopic compositions will be expressed throughout as percent deviations from the terrestrial atmospheric value.) The present-day Martian atmosphere is characterized by a value of plus 62 percent but this enrichment in (15)N is attributed to selective loss of (14)N from the Martian exosphere. Modelling of this fractionation leads to an estimated primordial composition similar to the terrestrial atmospheric value, through the precision of this model-dependent result is unclear. Author

VOLATILES, RHEOLOGY, AND MANTLE CONVECTION: COMPARING EARTH, VENUS, AND MARS Abstract Only **c90**
Walter S. Kiefer *In its* Conference on Deep Earth and Planetary Volatiles 1994 p 25 (For primary document see N95-21777 06-46)
Avail: CASI HC A01/MF A01

Silicate rheology is controlled in part by volatile content. The variation of viscosity with position in the mantle will influence the nature of mantle convection; hence, modeling mantle convection and its effect on surface observables such as the geoid places constraints on the viscosity structure of a planet's mantle and may indirectly constrain the volatile distribution. Models of viscous mantle flow and the Earth's geoid indicate that there is roughly a two order of magnitude variation in viscosity between the upper and lower mantles, although there is some disagreement over the depth of the viscosity minimum in the upper mantle. Some studies of post-glacial rebound also support such a viscosity contrast between the upper and lower mantles. On Venus, several highland regions appear to be supported by mantle plumes. Modeling of the geoid and topography of these regions indicates that if these features are plume-related, then the mantle of Venus can not have an Earth-like low viscosity zone in its upper mantle. On Mars, the Tharsis volcanic province has alternatively been explained as supported either by mantle convection or by flexure of a thick lithosphere. If the convective model is correct, then the large geoid anomaly requires that Mars can not have a low viscosity zone in its upper mantle. Author

SUBDUCTION AND VOLATILE RECYCLING IN EARTH'S MANTLE Abstract Only

S. D. King, J. J. Ita (California Inst. of Tech., Pasadena, CA.), and H. Staudigel (Vrije Univ., Amsterdam, Netherlands.) *In* Lunar and Planetary Inst., Conference on Deep Earth and Planetary Volatiles 1994 p 26 (For primary document see N95-21777 06-46)

Avail: CASI HC A01/MF A01

The subduction of water and other volatiles into the mantle from oceanic sediments and altered oceanic crust is the major source of volatile recycling in the mantle. Until now, the geotherms that have been used to estimate the amount of volatiles that are recycled at subduction zones have been produced using the hypothesis that the slab is rigid and undergoes no internal deformation. On the other hand, most fluid dynamical mantle flow calculations assume that the slab has no greater strength than the surrounding mantle. Both of these views are inconsistent with laboratory work on the deformation of mantle minerals at high pressures. We consider the effects of the strength of the slab using two-dimensional calculations of a slab-like thermal downwelling with an endothermic phase change. Because the rheology and composition of subducting slabs are uncertain, we consider a range of Clapeyron slopes which bound current laboratory estimates of the spinel to perovskite plus magnesiowustite phase transition and simple temperature-dependent rheologies based on an Arrhenius law diffusion mechanism. In uniform viscosity convection models, subducted material piles up above the phase change until the pile becomes gravitationally unstable and sinks into the lower mantle (the avalanche). Strong slabs moderate the 'catastrophic' effects of the instabilities seen in many constant-viscosity convection calculations; however, even in the strongest slabs we consider, there is some retardation of the slab descent due to the presence of the phase change. Author

VOLATILES IN THE DEEP EARTH: AN EXPERIMENTAL STUDY USING THE LASER-HEATED DIAMOND CELL Abstract Only

Xiaoyuan Li, Raymond Jeanloz, and Jeffrey H. Nguyen *In* Lunar and Planetary Inst., Conference on Deep Earth and Planetary Volatiles 1994 p 27 (For primary document see N95-21777 06-46)

Avail: CASI HC A01/MF A01

Experiments with the laser-heated diamond cell show that H2O and CO2 can be stabilized within crystalline mineral structures of the lower-mantle, and hence can be present at relatively non-volatile components of the Earth's deep interior. Samples quenched from high pressures and temperatures document that the MgCO3-FeCO3 magnesite-siderite solid-solution is stable and coexists with (Mg,Fe)SiO3 perovskite at 30-40 GPa and approximately 1500-2000 K. In contrast, H2O combines with the silicate to form (Mg,Fe)SiH2O4 phase D, coexisting with (Mg,Fe)SiO3 perovskite at these conditions. If enough water is present, phase D can become the predominant phase in the MgSiO3-H2O system at lower-mantle conditions. Our work extends previous studies to Fe-bearing compositions and to the pressures of the mid-lower mantle. Thus, the results of high-pressure experiments suggest that both H2O and CO2 can be abundant in the Earth's lower mantle, being present in stable hydroxisilicate and carbonate phases. Author

ALKALI ELEMENT DEPLETION BY CORE FORMATION AND VAPORIZATION ON THE EARLY EARTH Abstract Only

K. Lodders and B. Fegley, Jr. *In* Lunar and Planetary Inst., Conference on Deep Earth and Planetary Volatiles 1994 p 28 (For primary document see N95-21777 06-46)

Avail: CASI HC A01/MF A01

The depletion of Na, K, Rb, and Cs in the Earth's upper mantle and crust relative to their abundances in chondrites is a long standing problem in geochemistry. Here we consider two commonly invoked mechanisms, namely core formation, and vaporization, for producing the observed depletions. Our models predict that a significant percentage of the Earth's bulk alkali element inventory is in the core (30 percent for Na, 52 percent for K, 74 percent for Rb, and 92 percent for Cs). These predictions agree with independent estimates from nebular volatility trends and (for K) from terrestrial heat flow data. Our models also predict that vaporization and thermal escape during planetary accretion are unlikely to produce the observed alkali element depletion pattern. However, loss during the putative giant impact which formed the Moon cannot be ruled out. Experimental, observational, and theoretical tests of our predictions are also described. Alkali element partitioning into the Earth's core was modeled by assuming that alkali element partitioning during core formation on the aubrite parent body (APB) is analogous to that on the early Earth. The analogy is reasonable for three reasons. First, the enstatite meteorites are the only known meteorites with the same oxygen isotope systematics as the Earth-Moon system. Second, the large core size of the Earth and the V depletion in the mantle requires accretion from planetesimals as reduced as the enstatite chondrites. Third, experimental studies of K partitioning between silicate and metal plus sulfide show that more K goes into the metal plus sulfide at higher pressures than at one atmosphere pressure. Thus partitioning in the relatively low pressure natural laboratory of the APB is a good guide to alkali elemental partitioning during the growth of the Earth. Author

THE RATIOS OF CARBON AND NON-RADIOGENIC HELIUM AND ARGON ISOTOPES IN THE MANTLE AND CRUSTAL ROCKS Abstract Only

K. Lokhov and L. Levsky *In* Lunar and Planetary Inst., Conference on Deep Earth and Planetary Volatiles 1994 p 29 (For primary document see N95-21777 06-46)

Avail: CASI HC A01/MF A01

The studies of the relations of carbon and primary isotopes of noble gases were carried out on the natural gases and on the mantle rocks from the mantle M-type sources, which represent the degassed mantle reservoir (MORB's). These works has the aim of estimation of the values of the C/3He ratios in the deep mantle fluids to determine the flux of the mantle CO2 on the basis of known flux of primary mantle 3He. It was found, that in the natural gases the values of the C/3He ratios fall into the range from 1 times E plus 6 to 1 times E plus 15, and in the fluids of MORB's are constant near 2 times E plus 9. We have studied the mantle rocks from the relatively undergassed mantle P minus type sources: continental; Baikal Rift (Siberia), Mongolia, Catalonia (Spain), Pannonia Depression (central Europe) and ocean; Spietzbergen isl., Hawaii isl., Canarian isl. It ws found, that in mantle xenolites and the host alkaline basalts from the continental rifts and ocean islands, the values of the C/3He ratios fall into the range from E plus 11 to E plus 15 (and this result needed to be explained; the higher carbon to helium ratios is relatively undergassed mantle reservoir compared with the degassed one, requires whether hilly compatibility of helium compared with carbon, whether additional flux of 3He to the degassed mantle reservoir). From the other hand it was found that in the mantle rocks from the sources of P minus and M minus types, continental carbonatites, the values of the C/36Ar ratios are constant in the range from E plus 9 to E plus 10, the close values have the MORB's also. SOLAR SYSTEM FORMATION AND THE DISTRIBUTION OF VOLATILE SPECIES Abstract Only **c90**

Jonathan I. Lunine *In* Lunar and Planetary Inst., Conference on Deep Earth and Planetary Volatiles 1994 p 30-31 Sponsored by NASA (For primary document see N95-21777 06-46)

Avail: CASI HC A01/MF A01

To understand how the solar system formed we must understand the compositional distribution of the current system. Volatile species are particularly important in that their stability as condensed phases is limited in temperature-pressure space, and hence variations in their distribution at present potentially contain an imprint of processes by which temperature and pressure varied in the solar nebula. In this talk we restrict ourselves to species more volatile than water ice, and address issues related to processes in the outer solar system and the formation of bodies there; others in this conference will cover volatile species relevant to inner solar system processes. Study of the outer solar system is relevant both to understanding the interface between the solar nebula and the progenitor giant molecular cloud (since the chemical links to present-day observables in molecular clouds are species like methane, carbon monoxide, etc.), as well as the origin of terrestrial planet atmospheres and oceans (the latter to be covered by Owen). The wealth of compositional information on outer solar system bodies which has become available from spacecraft and ground-based observations challenges traditional simplistic views of the composition and hence dynamics of the solar nebula. The basic assumption of thermochemical equilibrium, promulgated in the 1950's, in which methane and ammonia dominate nitrogen- and carbon-bearing species, is demonstrably incorrect on both observational and theoretical grounds. However, the kinetic inhibition model which replaced it, in which carbon monoxide and molecular nitrogen dominate a nebula which is fully mixed and hence cycles outer solar system gases through a hot, chemically active zone near the disk center, is not supported either by observations. Instead, a picture of the outer solar system emerges in which the gas and grains are a mixture of relatively unaltered, or modestly altered, molecular cloud material, along with a fraction which has been chemically altered in the solar nebula itself (and perhaps giant planet nebulae). SOLUBILITIES OF NITROGEN AND NOBLE GASES IN BASALT MELT Abstract Only

A. Miyazaki, H. Hiyagon, and N. Sugiura *In* Lunar and Planetary Inst., Conference on Deep Earth and Planetary Volatiles 1994 p 32 (For primary document see N95-21777 06-46)

Avail: CASI HC A01/MF A01

Nitrogen and noble gases are important tracers in geochemistry and chosmochemistry. Compared to noble gases, however, physicochemical properties of nitrogen, such as solubility in melt or melt/silicate partition, are not well known. Solubility of nitrogen in basalt melt depends on redox condition of the atmosphere. For example, solubility of nitrogen in E chondrite melt under reducing conditions is as high as 2 mol percent at 1500 C, suggesting that nitrogen is chemically dissolved in silicate melts, i.e., being dissolved as free anions or replacing oxygen sites in silicate network. However, the solubility and the dissolution mechanism of nitrogen under oxidizing conditions are not well investigated. To obtain nitrogen solubility in silicate melts under various redox conditions and to understand its mechanism, we are conducting experiments by using (15)N(15)N-labeled nitrogen gas. This makes it easy to distinguish dissolved nitrogen from later contamination of atmospheric nitrogen, and hence enables us to measure the nitrogen solubility accurately. As a preliminary experiment, we have measured solubility of nitrogen in basalt melt under the atmospheric oxygen pressure. Author

SEISMIC EVIDENCE FOR VOLATILES AT LARGE DEPTH IN THE EARTH Abstract Only

Guust Nolet *In* Lunar and Planetary Inst., Conference on Deep Earth and Planetary Volatiles 1994 p 33 (For primary document see N95-21777 06-46)

Avail: CASI HC A01/MF A01

High resolution tomographic images that have been obtained of the subduction zones in the west Pacific do not only show very low P wave velocities above the leading edge of the slab at shallow depth, but also below 300 km. The two zones are generally, but not always, separated by a zone of normal shear velocity near 200 km depth. These findings confirm some earlier inferences from local seismic data in Japan, and similar findings of low Vp and low Q zones beneath South America. Surprisingly, such deep seismic low velocity zones have recently also been discovered beneath the locations of ancient subduction zones. A study of upper mantle shear velocity in Central Europe shows a similar distribution of low velocity zones beneath the Tornquist-Teisseyre line, the former west coast of the old continent of Baltica, and the site of the subducting Tornquist ocean in the early Palezoic. Preliminary results from a Russian-French experiment shows low P velocities below 250 km under the Urals, while an older tomographic study shows such low P velocities beneath the northern Appalachians. RATES OF EARTH DEGASSING Abstract Only

R. K. ONions *In* Lunar and Planetary Inst., Conference on Deep Earth and Planetary Volatiles 1994 p 34 (For primary document see N95-21777 06-46)

Avail: CASI HC A01/MF A01

The degassing of the Earth during accretion is constrained by Pu-U-I-Xe systematics. Degassing was much more efficient during the first 100-200 Ma than subsequently, and it was more complete for Xe than for the lighter gases. More than 90 percent of the degassed Xe escaped from the atmosphere during this period. The combination of fractional degassing of melts and rare gas escape from the atmosphere is able to explain the deficit of terrestrial Xe as a simple consequence of this early degassing history. By the time Xe was quantitatively retained in the atmosphere, the abundances of Kr and the lighter gases in the Earth's interior were similar to or higher than the present-day atmospheric abundances. Subsequent transfer of these lighter rare gases into the atmosphere requires a high rate of post-accretion degassing and melt production. Considerations of Pu-U-Xe systematics suggest that relatively rapid post-accretion degassing was continued to ca. 4.1-4.2 Ga. The present-day degassing history of the Earth is investigated through consideration of rare gas isotope abundances. Although the Earth is a highly degassed body, depleted in rare gases by many orders of magnitude relative to their solar abundances, it is at the present-day losing primordial rare gases which were trapped at the time of accretion. Studies of element abundances and values of D/H in the atmospheres of the giant planets and Titan have emphasized the important role of icy planetesimals in the formation of these bodies. In these atmospheres, C/H and D/H increase as the relative masses of the 'cores' of the planets increase. N/H appears to deviate from this trend in an interesting way. In the inner solar system, the traditional approach of using carbonaceous chondrites as the source of planetary volatiles is in serious trouble because of the depletion of xenon and the unusual pattern of xenon isotopes found in the atmospheres of Earth and Mars, and because of the solar-type abundance ratios of argon, krypton and xenon and the large amounts of neon and argon on Venus. Recent studies of elemental abundances in comets, especially P/Halley, coupled with laboratory studies of the trapping of gas in ice formed at low temperatures by A. Bar-Nun et al. provide a consistent interpretation of all of these results. This interpretation emphasizes the fundamental importance of icy planetesimals (comets) and the randomness of early impacts in the formation of planetary systems. Cometary delivery by itself will not explain the noble gas abundances on the inner planets. There is good evidence for at least one additional scurce, which presumably consists of the rocky material making up the bulk of the planets. The existence of this rocky reservoir is manifested in the nucleogenic isotopes and in the neon which is found in all these atmospheres and is also present in the Earth's mantle. This neon may well be a relic of the planets' earliest, accretional atmospheres. Author

POLAR VOLATILES ON MERCURY AND THE MOON Abstract Only c91

D. A. Paige, S. E. Wood, and A. R. Vasavada (California Inst. of Tech., Pasadena, CA.) *In* Lunar and Planetary Inst., Conference on Deep Earth

and Planetary Volatiles 1994 p 36 (For primary document see N95-21777 06-46)
Avail: CASI HC A01/MF A01

The possibility that condensed volatiles might be stable in the permanently shadowed polar regions of the Moon and Mercury has been anticipated in a number of theoretical studies. In 1992, VLA-Goldstone and Arecibo observations revealed the presence of bright, depolarized radar features near the poles of Mercury that have been widely interpreted as evidence for the presence of polar ice deposits. Recently acquired high-resolution Arecibo radar images show that the anomalous radar features are concentrated in crater-sized regions whose locations can be made to coincide exactly with the locations of known impact craters in the Mariner-10 images. These new Arecibo images provide an unusual opportunity to learn more about the distribution and history of Mercury's polar ice deposits. We have constructed a thermal model that can predict surface and subsurface temperatures within impact craters on Mercury and the Moon. Included in the calculations are the effects of 1-dimensional subsurface heat conduction, direct sunlight, multiply reflected sunlight within the crater, and re-radiated infrared radiation within the crater. We also use realistic crater topographic profiles for larger flat-floored craters as well as smaller spherical bowl-shaped craters. Author

MANTLE RARE GAS RELATIVE ABUNDANCES IN A STEADY-STATE MASS TRANSPORT MODEL Abstract Only
D. Porcelli and G. J. Wasserburg *In* Lunar and Planetary Inst., Conference on Deep Earth and Planetary Volatiles 1994 p 37 (For primary document see N95-21777 06-46)
Avail: CASI HC A01/MF A01

A model for He and Xe was presented previously which incorporates mass transfer of rare gases from an undegassed lower mantle (P) and the atmosphere into a degassed upper mantle (D). We extend the model to include Ne and Ar. Model constraints on rare gas relative abundances within P are derived. Discussions of terrestrial volatile acquisition have focused on the rare gas abundance pattern of the atmosphere relative to meteoritic components, and the pattern of rare gases still trapped in the Ear,th is important in identifying volatile capture and loss processes operating during Earth formation. The assumptions and principles of the model are discussed in Wasserburg and Porcelli (this volume). For P, the concentrations in P of the decay/nuclear products 4 He, 21 Ne, 40 Ar, and 136 Xe can be calculated from the concentrations of the parent elements U, Th, K, and Pu. The total concentration of the daughter element in P is proportional to the isotopic shifts in P. For Ar, ((40)Ar/(36)Ar)p - ((40)Ar/(36)Ar)o =Delta (exp 40) p= 40 Cp/(exp 36)C where(i)C(sub j) the concentration of isotope i in j. In D, isotope compositions are the result of mixing rare gases from P, decay/nuclear products generated in the upper mantle, and subducted rare gases (for Ar and Xe). Author

HYDROGEN STORAGE IN EARTH'S MANTLE AND CORE Abstract Only
Charles T. Prewitt *In* Lunar and Planetary Inst., Conference on Deep Earth and Planetary Volatiles 1994 p 38 (For primary document see N95-21777 06-46)
Avail: CASI HC A01/MF A01

Two different approaches to explaining how hydrogen might be stored in the mantle are illustrated by a number of papers published over the past 25-30 years, but there has been little attempt to provide objective comparisons of the two. One approach invokes the presence in the mantle of dense hydrous magnesium silicates (DHMS) stable at elevated pressures and temperatures. The other involves nominally anhydrous minerals (NAM) that contain hydrogen as a minor constituent on the ppm level. Experimental studies on DHMS indicate these phases may be stable to pressures and temperatures as high at 16 GPa and 1200 C. This temperature is lower than that indicated by a mantle geotherm at 16 GPa, but may be reasonable for a subducting slab. It is possible that other DHMS could be stable to even higher pressures, but little is known about maximum temperature limits. For NAM, small amounts of hydrogen (up to several hundred ppm) have been detected in olivine, orthopyroxene, clinopyroxene, and garnet recovered from xenoliths in kimberlites, eclogites, and alkali basalts; it has been demonstrated that synthetic wadsleyite and perovskite can accommodate significant amounts of hydrogen. A number of problems are associated with each possibility. For NAM originating in the mantle, one would like to assume that the hydrogen measured in samples recovered on Earth's surface was incorporated when the phase-crystallized at high temperatures and pressures, but it could have been introduced during transport to the surface. Major problems for the DHMS proponents are that none of these phases have been found as minerals and little is yet known about their stabilities in systems containing other cations such as Fe, Al, and Ca. SUBDUCTION OF HYDRATED BASALT OF THE OCEANIC CRUST: IMPLICATIONS FOR RECYCLING OF WATER INTO THE UPPER MANTLE AND CONTINENTAL GROWTH Abstract Only
R. P. Rapp *In* Lunar and Planetary Inst., Conference on Deep Earth and Planetary Volatiles 1994 p 39 (For primary document see N95-21777 06-46)
Avail: CASI HC A01/MF A01

Subduction zones are presently the dominant sites on Earth for recycling and mass transfer between the crust and mantle; they feed hydrated basaltic oceanic crust into the upper mantle, where dehydration reactions release aqueous fluids and/or hydrous melts. The loci for fluid and/or melt generation will be determined by the intersection of dehydration reaction boundaries of primary hydrous minerals within the subducted lithosphere with slab geotherms. For metabasalt of the oceanic crust, amphibole is the dominant hydrous mineral. The dehydration melting solidus, vapor-absent melting phase relationships; and amphibole-out phase boundary for a number of natural metabasalts have been determined experimentally, and the pressure-temperature conditions of each of these appear to be dependent on bulk composition. Whether or not the dehydration of amphibole is a fluid-generating or partial melting reaction depends on a number of factors specific to a given subduction zone, such as age and thickness of the subducting oceanic lithosphere, the rate of convergence, and the maturity of the subduction zone. In general, subduction of young, hot oceanic lithosphere will result in partial melting of metabasalt of the oceanic crust within the garnet stability field; these melts are characteristically high-Al_2O_3 trondhjemites, tonalites and dacites. The presence of residual garnet during partial melting imparts a distinctive trace element signature (e.g., high La/Yb, high Sr/Y and Cr/Y combined with low Cr and Y contents relative to demonstrably mantle-derived arc magmas). Water in eclogitized, subducted basalt of the oceanic crust is therefore strongly partitioned into melts generated below about 3.5 GPa in 'hot' subduction zones. Although phase equilibria experiments relevant to 'cold' subduction of hydrated natural basalts are underway in a number of high-pressure laboratories, little is known with respect to the stability of more exotic hydrous minerals (e.g., ellenbergite) and the potential for oceanic crust (including metasediments) to transport water deeper into the mantle. Avail: CASI HC A01/MF A01

Planetary volatile inventories are products of several factors: (1) condensation-accretion of pre-planetary material which determines the bulk volatile inventory; (2) energy history of a planet, including timing, causes, and mechanisms of degassing; (3) the volatile sinks, including temporary, long term, and permanent; and (4) external processes operating on the volatile inventory. Information regarding the current surface compositions provide insight into both internal and surface-atmosphere evolutionary history. Our discussion focuses upon the surface composition of outer solar system planets and satellites as determined by spacecraft and telescopic spectral observations. We provide a review and an update of the recent work by Cruikshank and Brown that includes more recent observations and interpretations. In the context of formation and evolution of solar system bodies, the interesting ices typically considered are simple molecules formed from elements having high cosmic abundances. These mainly include ices of H_2O, NH_3, SO_2, H_2S, CH_4, CO, CO_2, and N_2. In the solid state, these ices have vibrational spectral features, analogous to their gaseous counterparts but rotational transitions are quenched, that lie in the near- and mid-infrared. The overtone and combination modes, occurring in the visible and near-IR region, are of particular importance as standard observational techniques used to identify these ices rely upon reflected solar energy. Table I summarizes the ices found on various bodies in the outer solar system. H2O is most abundant surface material in the inner and middle regions while more volatile species appear to dominate surfaces in the outermost edge of the outer solar system. Author

DEGASSING HISTORY AND EVOLUTION OF VOLCANIC ACTIVITY OF TERRESTRIAL PLANETS BASED ON RADIOGENIC NOBLE GAS DEGASSING MODELS Abstract Only **c91**
S. Sasaki and E. Tajika *In* Lunar and Planetary Inst., Conference on Deep Earth and Planetary Volatiles 1994 p 42 (For primary document see N95-21777 06-46)
Avail: CASI HC A01/MF A01

Current abundances of radiogenic noble gases (4-He, 40-Ar, 129-Xe) in the planetary atmospheres provide valuable information on planetary evolution through their degassing histories. Of these, 40-Ar (from 40-K with half life 1.25 Ga) can be used to envisage long-term degassing from their interior. Present amounts of 36 and 40-Ar should have information on timing and degree of degassing from the interior. On the other hand, 129-Xe (from 129-I with half life 17 Ma) is used in discussing early planetary degassing. Because life time of helium in the atmosphere is short, atmospheric 4-He (from 235-U, 238-U, 232-Th) data might be used only for current degassing. The relative abundance of 40-Ar in the Cytherean atmosphere is 0.26 of that in the Earth's atmosphere. We have executed numerical calculation of a 40-Ar degassing model along with mantle evolution and melt migration. Our result shows that the average magma production rate on Venus is about 5 (km(exp 3)/yr). Duration of plate motion on Venus, if existed, would be less than several hundred million years. Author

A CRYSTALLOGRAPHIC MODEL FOR HYDROUS WADSLEYITE (BETA-Mg2SiO4) Abstract Only
J. R. Smyth *In* Lunar and Planetary Inst., Conference on Deep Earth and Planetary Volatiles 1994 p 43 (For primary document see N95-21777 06-46)
Avail: CASI HC A01/MF A01

Wadsleyite (beta-Mg2SiO4) is believed to be the most abundant phase in the Earth between depths of 400 and about 525km. Because of the unusual crystal chemistry, Smyth suggested that this phase might be a significant host for hydrogen in the transition zone. Indeed, of the nominally anhydrous phases believed to make up the upper mantle and transition zone none has been reported with a greater H content than wadsleyite. Young et al, report the synthesis of hydrous, Fe-bearing wadsleyite with up to 60,000 H per 10(exp 6) Si. Using ionic constraints and maximal subgroup symmetry, a hypothetical, ordered model for hydrous wadsleyite has been created and examined. The model has formula Mg7Si4O14(OH)2, has space group Pmmb, has an ordered vacancy into one of two non-equivalent M2 sites, and contains two different H positions, one on each of the non-equivalent O1 sites. Electrostatic calculations indicate that hydration would relieve the underbonding of O1 as well as the overbonding of the bridging oxygen, O2, so that the hydrous phase may be more stable than the anhydrous phase. This model makes several predictions that may be of significance for the mechanisms and amounts of H that may be stored in the transition zone of the Earth, and by which the model may be tested experimentally. SEMI-VOLATILES AT MERCURY: SODIUM (Na) AND POTASSIUM (K) Abstract Only **c91**
A. Sprague *In* Lunar and Planetary Inst., Conference on Deep Earth and Planetary Volatiles 1994 p 44 (For primary document see N95-21777 06-46)
Avail: CASI HC A01/MF A01

Several lines of evidence now suggest that Mercury is a planet rich in moderately-volatile elements such as Na and K. Recent mid-infrared spectral observations of Mercury's equatorial and mid-latitude region near 120 degrees mercurian longitude indicate the presence of plagioclase feldspar. Spectra of Mercury's surface exhibit spectral activity similar to labradorite (plagioclase feldspar with NaAlSi3O8: 30-50 percent) and bytownite (NaAlSi3O8: 10-30 percent). These surface studies were stimulated by the relatively large abundance of Na and K observed in Mercury's atmosphere. An enhanced column of K is observed at the longitudes of Caloris Basin and of the antipodal terrain. Extreme heating at these 'hot' longitudes and severe fracturing suffered from the large impact event could lead to enhanced outgassing from surface or subsurface materials. Alternatively, sputtering from a surface enriched in K could be the source of the observed enhancement. Recent microwave measurements of Mercury also give indirect evidence of a mercurian regolith less FeO-rich than the Moon. An anomalously high index of refraction derived from the whole-disk integrated phase curve of Danjon may also be indicative of surface sulfides contributing to a regolith that is moderately volatile-rich. The recent exciting observations of radar-bright spots at high latitudes also indicate that a substance of high volume scattering, like ice, is present in shadowed regions. Other radar-bright spots have been seen at locations of Na enhancements on the atmosphere. All combined, these pieces of evidence point to a planet that is not severely depleted in volatiles or semi-volatiles. Author

IMPLICATIONS OF NOBLE GASES IN A RECENTLY RECOGNIZED MARTIAN METEORITE (ALH84001) FOR THE DEGASSING HISTORY OF MARS Abstract Only **c91**
T. D. Swindle *In* Lunar and Planetary Inst., Conference on Deep Earth and Planetary Volatiles 1994 p 45 (For primary document see N95-21777 06-46)
Avail: CASI HC A01/MF A01

For terrestrial planets, atmospheric compositions are not static, but evolve with time, in part due to degassing of the interior. Unfortunately, the evolution is slow enough that it is usually not observable on human timescales, or even on the timescales of rocks that preserve samples of Earth's ancient atmosphere. Preliminary results on a recently recognized Martian meteorite, ALH84001, indicate that it is a very old rock, and has a relatively high noble gas content suggestive of atmospheric incorporation, but with an isotopic composition slightly inconsistent with currently known Martian reservoirs. Hence, this rock may provide a sample of ancient Martian atmosphere, which can be used to test models of volatile evolution (in particular, degassing) on Mars. ALH84001 is a cumulate orthopyroxenite. Although originally classified as a diogenite, its oxygen isotopes, and several chemical and petrographic features, strong suggest that it is, like the SNC meteorites, Martian. A Sm-Nd crystallization age of 4.5 Ga has been reported. The meteorite is rich in noble gases, compared to most SNC's. In many respects the noble gases are typical of SNC meteorites. However, there are some subtle differences. In particular, the Xe isotopes in SNC meteorites can be explained as a mixture of Martian atmospheric Xe (as represented by glass in EETA 79001), the Xe in the dunite Chassigny (usually assumed to be representative of the Martian interior, and with lower (129)Xe/(132)Xe, (134)Xe/(132)Xe and (136)Xe/(132)Xe ratios), and later additions from known processes like fission, spallation and terrestrial contamination. The isotopic composition of ALH84001 is inconsistent (at greater than 2-3 sigma) with any mixture of those components. Even if no accumulation of fission Xe during the age of the rock is assumed, there is too little (136)Xe and (134)Xe for the amount of (129)Xe measured. Author

WATER ABUNDANCE AND ACCRETION HISTORY OF TERRESTRIAL PLANETS Abstract Only
H. Waenke and G. Dreibus *In* Lunar and Planetary Inst., Conference on Deep Earth and Planetary Volatiles 1994 p 46 (For primary document see N95-21777 06-46)
Avail: CASI HC A01/MF A01

According to a widespread believe, Earth's water was either added in form of a late volatile-rich veneer or as we have argued repeatedly that of all the water which was added to the Earth only that portion remained which was added towards the end of accretion when the mean oxygen fugacity of the accreting material became so high that metallic iron could not exist any longer. Prior to this moment, all the water in the latter scenario would have been used up for the oxidation of iron. Fe + H2O yields FeO + H2. Huge quantities of hydrogen would continuously be produced in this scenario which escaped. In the same moment the hydrogen on its way to the surface would lead to an efficient degassing of the growing Earth's mantle. The fact that - assuming C1 abundances - the amount of iridium in the Earth's mantle agrees, within a factor of two with the total water inventory of the Earth's mantle and crust is taken as evidence for the validity of such a scenario. In both scenarios, the Earth's mantle would remain dry and devoid of other volatiles. Some species soluble in metallic iron like carbon and hydrogen will probably partly enter the core in some portions. It is generally assumed that today a considerable portion of the earth's total water inventory resides in the mantle. It is also clear that over the history of the Earth the water of the Earth's oceans has been recycled many times through the mantle. This is the consequence of plate subduction. In a similar way mantle convection was probably responsible to being water into the originally dry mantle. As a consequence, today the Earth is wet both inside and outside. Author

He, Xe AND Ne ISOTOPES IN A STEADY-STATE MASS TRANSPORT MODEL AND IMPLICATIONS ABOUT TERRESTRIAL VOLATILES Abstract Only
G. J. Wasserburg and D. Porcelli *In* Lunar and Planetary Inst., Conference on Deep Earth and Planetary Volatiles 1994 p 47 (For primary document see N95-21777 06-46)
Avail: CASI HC A01/MF A01

We present a model of the steady-state transport assuming three reservoirs: a lower mantle (P) with a relatively undepleted inventory of U, Th, Pu, I, He, Ne, Xe, Ar; an upper mantle that has been extensively outgassed (D); and the atmosphere. There is mass transport at a rate M(sub PD) by plumes from the lower mantle, a fraction of which is outgassed directly into the atmosphere, while the remainder feeds matter and associated nuclei into D. D is well outgassed at spreading centers and has material containing atmospheric gases added to it by subduction. In the case of He, there is no subduction component. The approach follows the treatment of Kellogg and Wasserburg. A summary of the pertinent equations and constraints was reported earlier. The U, Th and Pu in P are estimated for Earth models from refractory element abundances in meteorites. In this model the inventory of rare gases in D is governed by the simple mixing of components from P (both radiogenic and original) with distinctive atmospheric components. In addition, alpha decay and spontaneous fission of U, and (alpha, n) reaction on oxygen from energetic alpha particles produce radiogenic/nuclear daughter products in D. These include (4)He, (136)Xe and (21)Ne. (40)K in D generates excess radiogenic (40)Ar. Author

STORAGE AND RECYCLING OF WATER AND CARBON DIOXIDE IN THE EARTH Abstract Only
Bernard J. Wood *In* Lunar and Planetary Inst., Conference on Deep Earth and Planetary Volatiles 1994 p 48-49 (For primary document see N95-21777 06-46)
Avail: CASI HC A01/MF A01

The stabilities and properties of water- and carbon-bearing phases in the earth have been determined from phase equilibrium measurements, combined with new data on the equations of state of water, carbon dioxide, carbonates and hydrates. The data have then been used to predict the fate of calcite and hydrous phases in subducting oceanic lithosphere. From the compositions of MORB's one can estimate concentrations of water and carbon of around 200 ppm and 80 ppm respectively in the upper mantle. Lower mantle estimates are very uncertain, but 1900 ppm water and 2000 ppm C are plausible concentrations. Measurements of the density of supercritical water to 3 GPa demonstrate that this phase is less compressible than anticipated from the equations of state of Haar et al. or Saul and Wagner and is closer to predictions based on molecular dynamics simulations. Conversely, fugacity measurements on carbon dioxide to 7 GPa show that this fluid is more compressible than predicted from the MRK equation of state. The results imply that hydrates are relatively more stable and carbonates less stable at pressures greater than 5 GPa than would be predicted from simple extrapolation of the low pressure data. Nevertheless, carbonates remain extremely refractory phases within both the upper and lower mantle. Author

IS XENON ELDEST? Abstract Only
K. Zahnle *In* Lunar and Planetary Inst., Conference on Deep Earth and Planetary Volatiles 1994 p 50 (For primary document see N95-21777 06-46)
Avail: CASI HC A01/MF A01

It is well known that the solubility of noble gases in magmas decreases with increasing atomic weight. Xenon, the weightiest of the stable noble gases, is the least soluble atmospheric gas in magma. It is not unreasonable to suppose that the noble gases should have degassed from (or equilibrated with) a bubbling mantle in order of increasing solubility, such that xenon was the most rapidly degassed and helium the least. The apparent relative ages of the famous radiogenic noble gas isotopes agrees, at least qualitatively, with this premise. When atmospheric loss processes are assigned their proper place, several long-standing xenonological puzzles become added evidence for xenon's relative antiquity. Xenon being the afore-mentioned sense the oldest atmospheric gas, will have been most greatly subject to escape, be it impact-driven or EUV-driven. Nonradiogenic xenon's pronounced isotopic fractionation has already been attributed to escape; why it should be more fractionated than krypton would be assigned to xenon's greater atmospheric age. The small atmospheric inventory of xenon relative to the other nonradiogenic noblegases, known as the 'missing xenon' problem, could easily be explained by differential escape. The relatively tiny atmospheric inventories of the radiogenic daughter products of 129 Iodine and 244 Plutonium, both much smaller than would be expected from the inferred abundances of the parents in meteorites, offer a third and fourth data to support the hypothesis that Earth has lost most of its xenon. DEGASSING MECHANISMS OF NOBLE GASES FROM CARBONADO DIAMONDS Abstract Only
S. Zashu and H. Hiyagon *In* Lunar and Planetary Inst., Conference on Deep Earth and Planetary Volatiles 1994 p 51 (For primary document see N95-21777 06-46)
Avail: CASI HC A01/MF A01

Diamonds are unique samples for inferring ancient mantle conditions, because of their enormous stability, antiquity and also of mantle origin. However, as temperatures in the mantle where diamonds have existed are very high (greater than 1000 C) and residence time of some diamonds could be more than a few billion years, it is imperative to examine whether or not diamonds have retained their pristine characteristics, especially those of noble gases, under such extreme conditions. As discussed in a review article by Ozima, there are rather large variations in the diffusivity of helium in diamonds obtained in the early determinations. The data are also limited to temperatures higher than 1200 C. In the present study, we conducted more refined diffusion experiments for He using carbonado diamonds, which have large amounts of radiogenic (4)He approximately 10(exp -2) cu cm STP/g. On the basis of the experimentally estimated diffusion coefficients, we will discuss retentivity of He in diamonds in the mantle condition. Author

VARIABILITY OF TOTAL ELECTRON CONTENT IN THE HIGH-ALTITUDE IONOSPHERE FOLLOWING SOLAR MAXIMUM
C. C. Andreasen and Elizabeth Holland 9 Mar. 1994 20 p
(Contract F19628-92-C-0162)
(AD-A285849; NWRA-CR-94-R111; PL-TR-94-2078; SR-1) Avail: CASI HC A03/MF A01

Northwest Research Associates (NWRA) is recording a database containing measurements of the differential carrier phase (DCP) and the differential group delay (DGD) between the two L-band signals transmitted by satellites of the Global Positioning System (GPS). Data collection is continuing at Shemya, AK, and Hanscom AFB, MA. Software has been, and continues to be, developed to process these data into measurements of trans-ionospheric total electron content (TEC). This database is being analyzed in order to document the variability of TEC and to specify TEC morphology in the region of Shemya, AK. Studies of multipath mitigation and accurate satellite bias determination have been conducted to insure high data quality. Analysis of these and other data developed by NWRA in other high latitude studies in the Shetland Islands, UK, has yielded ionospheric trough boundary signatures. These data will be compared to Ionosphere, Morphology, Total electron content, Ionospheric trough. DTIC

STABILITY EFFECTS ON THE PROFILES OF VERTICAL VELOCITY AND ITS VARIANCE IN KATABATIC FLOW

R. L. Coulter and T. J. Martin 1994 7 p Presented at the 7th International Symposium on Acoustic Remote Sensing and Associated Techniques of the Atmosphere and Oceans, Boulder, CO, 3-7 Oct. 1994
(Contract W-31-109-eng-38)
(DE95-001126; ANL/ER/CP-82594; CONF-9410222-1) Avail: CASI HC A02/MF A01

The atmospheric katabatic flow in the foothills of the Front Range of the Rocky Mountains has been monitored by a network of towers and sodars for several years as part of the Atmospheric Studies in Complex Terrain (ASCOT) program. The dependence of the vertical component of motion, its variance, and the mean component of the wind perpendicular to the surface at the mouth of Coal Creek Canyon on surface cooling and channeling by winds above the canyon has been explored by using almost three years of data from the network. The magnitude of the near-surface temperature differences was found to decrease with increasing surface cooling in light winds, apparently because of increasing turbulence resulting when increasing winds interact with surface topography. The variance of vertical velocity exhibits three types of vertical profiles, corresponding to different cooling rates and external wind speeds. The mean variance was found to depend strongly on a locally derived Richardson number. DOE

POTENTIAL FLOW DOWNSTREAM OF THE HELIOSPHERIC TERMINAL SHOCK: A NON-SPHERICAL SHOCK

Steven Nerney and Steven T. Suess Oct. 1994 12 p Submitted for publication Sponsored by NASA
(NASA-TM-110493; NAS 1.15:110493) Avail: CASI HC A03/MF A01

We have solved for the potential flow downstream of the terminal shock of the solar wind in the limit of small departures from a spherical shock due to a latitudinal ram pressure variation in the supersonic solar wind. The solution connects anisotropic streamlines at the shock to uniform streamlines down the heliotail because we use a non-slip boundary condition on the heliopause at large radii. The rotational velocity about the heliotail in the near-field solution decays as the fourth power of distance from the shock. The polar divergence of the streamlines will have consequences for the previously discussed magnetic pressure ridge that may build-up just inside the heliopause. Author

HIGH RESOLUTION PROPERTIES OF THE EQUATORIAL PACIFIC MARINE ATMOSPHERIC BOUNDARY LAYER FROM LIDAR AND RADIOSONDE OBSERVATIONS

Daniel I. Cooper, William E. Eichinger, Mike V. Hynes, Charles F. Keller, Charles F. Lebeda, and David A. Poling 1994 7 p Presented at the 75th Annual Meeting of the American Meteorological Society: Diamond Anniversary, Dallas, TX, 15-20 Jan. 1995
(Contract W-7405-eng-36)
(DE95-001028; LA-UR-94-3103; CONF-950124-1) Avail: CASI HC A02/MF A01

Water vapor and relative aerosol concentration were measured with two shipboard lidars from the ocean surface to tropospheric and lower stratospheric altitudes in support of the Central Equatorial Pacific Experiment (CEPEX) program. The goal of CEPEX is to evaluate the 'thermostat' hypothesis regarding feedback mechanisms between the tropical ocean and the atmosphere. This paper describes some of the features observed with the first two kilometers of the equatorial troposphere, known as the marine Atmospheric Boundary Layer (ABL), as well as the coupling between the ocean and the atmosphere. This paper will present the initial analysis of the structure of the atmospheric boundary layer. Finally, we will look at the implications of this structure for ocean-atmosphere coupling by comparing the height of the mixing layer with sea surface temperatures and other factors. DOE

SOURCE CONTRIBUTIONS AT FAR-REGIONAL DISTANCES

Karl Koch and Brian Stump 12 Dec. 1993 94 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract F19628-91-K-0016)
(AD-A279405; PL-TR-94-2018; AD-E201929; SR-1) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

In order to investigate source contributions at far-regional distances (as far as 2,000 km), a reliable model of the upper mantle structure is necessary. In many cases successful discriminants are based on the S wave part of far-regional seismograms including Sn, Sg, Lg and surfaces waves. Therefore it is mandatory to place corresponding weight on constraining the upper mantle S wave structure for the region under consideration. This current report hence provides an investigation of the mantle shear structure for the Western U.S. from body and surface wave inversion. Earthquakes on the coast of northern California and off the coast of southern Oregon (5.5 less than Ms less than 7.1) have provided a set of data at LTX showing clear mantle S arrivals that become very impulsive at distances near 2,400 km. The great circle paths for these events to LTX coincide with the LTX-NTS path. These data allow the interpretation of the S velocity structure for the Western U.S. to depths of the upper mantle transition zone from the body waves and give constraints for the shallower structure from surface waves from inversion of Rayleigh and Love waves, summarized in the two papers contained in this report. SURFACE EXPOSURE GEOCHRONOLOGY USING COSMOGENIC NUCLIDES: APPLICATIONS IN ANTARCTIC GLACIAL GEOLOGY Ph.D. Thesis - MIT

Edward J. Brook Feb. 1994 234 p Sponsored in part by ONR Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Grants NSF DPP-91-17458; NSF DPP-88-17406)
(AD-A279392; WHOI-93-50) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Cosmogenic He(3), Al(26), and Be(10) were measured in Antarctic glacial deposits in the McMurdo Sound-Dry Valleys region to constrain surface exposure ages. Moraines deposited by the Taylor glacier, an outlet glacier of the East Antarctic Ice Sheet, have exposure ages from approx. 120 kyr to 2myr. Be(10), He(3) ages of 122 +/- 29 and 134+ / -54 kyr, respectively, for the Taylor II moraine are consistent with deposition during isotope stage 5e approx. 120 kyr. Mean Be(10) exposure ages for older moraines in the valley of 362 + or - 26 kyr (Taylor III), 1.1 + or 1 0.1 myr (Taylor IVa) and 1.9 + or - 0.1 myr (Taylor IVb) suggest that major ice sheet advances during the last 2 myr were similar in extent to changes during the last glacial-interglacial cycle. Exposure ages for the 'late Wisconsin' Ross Sea Drift, deposited on the coast of McMurdo Sound by the Ross Sea Ice Sheet, range from 8-106 kyr, suggesting that this deposit does not, as previously thought, represent a single ice advance in response to lowered sea level at the last glacial maximum. The data suggest instead that the Ross Sea Ice Sheet may have grounded and advanced on the coast several times during the last glacial period. DTIC

A SIMULATION OF PLASMA MOTION IN THE POLAR IONOSPHERE M.S. Thesis

David W. Deist Sep. 1994 52 p
(AD-A286166) Avail: CASI HC A04/MF A01

A model of plasma motion in the polar ionosphere is presented. Plasma motion due to polar convection and corotation above 50 deg N is modeled. The universal time (UT)-dependent corotation electric field (in the geomagnetic frame) is added to a polar convection electric field that is UT-dependent in the geographic frame and the total is displayed in both reference frames. To simulate actual magnetic conditions, varying polar convection patterns may be used by the model we have developed. Trajectories of single plasma parcels and regions of plasma are calculated. The calculated trajectories are displayed in the geographic and magnetic inertial reference frames. The model developed is applied to the study of a region of electron depletion near the pole, a polar hole. Changes in the size and location of the polar hole are explained in terms of a changing convection pattern. The results of this thesis are being used by the Johns Hopkins University Applied Physics Laboratory to further study ionospheric plasma motion. DTIC

VTT TEST BOREHOLE FOR BEDROCK INVESTIGATIONS
Olli Okko, Pertti Hassinen, and Kai Front Feb. 1994 42 p
(PB95-132965; VTT/RN-1538) Copyright Avail: Issuing Activity (National Technical Information Service (NTIS))

A borehole of depth 150 m and diameter 56 mm has been drilled in the area adjacent to the premises of the Technical Research Center of Finland (VTT) at Otaniemi, Espoo, for the purposes of calibrating geophysical measurement devices. The report presents the test results obtained so far and illustrates the processing of these, in which the various measurements are plotted as curves and combinations of curves. The interpretations provided so far consist of analyses of lithological variations, bedrock fracturing, the nature and occurrence of fracture zones and groundwater flow patterns. Samples were taken from those parts of the core shown by the borehole measurements to be homogeneous and thin sections made from these for mineralogical determinations. The rock mechanical and petrophysical properties of the same points were examined. The core is in the possession of VTT, and the hole itself is available to outsiders for the calibration and testing of borehole measurement equipment. NTIS

CONFIRMATORY ANALYSIS OF SAGE-1, AND -2 DATA Semiannual Progress Report, 30 Jun. - 30 Dec. 1994
David W. Rusch, Stanley C. Solomon, Cora E. Randall, and R. Todd Clancy 1994 3 p
(Contract DE-FG03-94ER-61856)
(DE95-003623; DOE/ER-61856/T1) Avail: CASI HC A01/MF A01

This study is motivated by the need for an independent assessment of the SAGE-1, and -2 data to determine the long-term tenacity of the data set and the inversion procedures used to handle the data. In particular, ozone measurements in the lower stratosphere, where our primary attention is focused, are complicated by the permanent presence of atmospheric aerosols. At times, the natural background aerosol density is complemented or even overwhelmed by volcanic injections which interfere with the normal data processing of instruments such as SAGE. This report summarizes progress on the grant for the first 6 months of the grant period ending 12/30/94. During this period we have collected the relevant SAGE data, purchased needed computers and equipment, designed the database, and outlined the forward model requirements and mathematical procedures. THRESHOLD DETECTION IN THE PRESENCE OF ATMOSPHERIC TURBULENCE
H. T. Yura 15 Oct. 1994 20 p
(Contract F04701-93-C-0094)
(AD-A286175; TR-94(4911)-1; SMC-TR-94-40) Avail: CASI HC A03/MF A01

Recently, there has been increased interest in threats to spacecraft from ground-based lasers. It has been suggested that some spacecraft should employ laser-threat warning receivers. Here, we consider the effects of atmospheric turbulence on threshold detection of optical signals by an exoatmospheric receiver. The present results are applicable to both cw and pulsed optical illumination from ground-based lasers. In particular, we obtain accurate analytical expressions, over a wide range of conditions of practical interest, that give the required signal-to-noise ratio for a given (single-event) probability of detection, false-alarm rate, and turbulence-induced log-intensity variance. The degrading effects of atmospheric turbulence on threshold detection are most important for large zenith angles in the blue-green region of the spectrum. As an illustrative example, a false-alarm rate of one in three years is assumed, and specific numerical results are presented for the required signal-to-noise ratio necessary to obtain a detection probability of at least 95% over a range of opticalwavelengths and propagation conditions of interest. Consensus on the timing and mapping of substorm features has permitted a synthesis of substorm models. Within the synthesis model the mechanism for onset of substorm expansion is still unknown. Possible mechanisms are: growth of an ion tearing mode, current disruption by a cross-field current instability, and magnetosphere-ionosphere coupling. While the synthesis model is consistent with overall substorm morphology, including near-Earth onset, none of the onset theories, taken individually, appear to account for substorm expansion onset. A grand synthesis with unification of the underlying onset theories appears necessary. Author

LARGE-SCALE FIELDS AND FLOWS IN THE MAGNETOSPHERE-IONOSPHERE SYSTEM
M. Lockwood Sep. 1994 56 p
(PB95-134664; RAL-94-097) Avail: Issuing Activity (National Technical Information Service (NTIS))

Advances in the author's understanding of the large-scale electric and magnetic fields in the coupled magnetosphere-ionosphere system are reviewed. The literature appearing in the period January 1991-June 1993 is sorted into 8 general areas of study. The phenomenon of substorms receives the most attention in this literature, with the location of onset being the single most discussed issue. However, if the magnetic topology in substorm phases was widely debated, less attention was paid to the relationship of convection to the substorm cycle. A significantly new consensus view of substorm expansion and recovery phases emerged, which was termed the 'Kiruna Conjecture' after the conference at which it gained widespread acceptance. The second largest area of interest was dayside transient events, both near the magnetopause and the ionosphere. It became apparent that these phenomena include at least two classes of events, probably due to transient reconnection bursts and sudden solar wind dynamic pressure changes. The contribution of both types of events to convection is controversial. Several new techniques were introduced including ionospheric observations which yield reconnection rate as a function of time. The magnetospheric and ionospheric behavior due to various quasi-steady interplanetary conditions was studied using magnetic cloud events. NTIS

(DE95-002739; LA-UR-94-3554; CONF-9408182-1) Avail: CASI HC A03/MF A01

This paper briefly summarizes the early studies of the Los Alamos Magnetospheric Plasma Analyzer (MPA) observations. The three MPA instruments presently on orbit are returning a unique set of simultaneous, multi-point observations of the geosynchronous plasma environment. So far, MPA studies can be divided into six general topics: (1) morphology and distribution of the plasma regions observed at geosynchronous orbit; (2) the location and shape of the magnetopause when compressed and/or eroded to within geosynchronous orbit; (3) rare geosynchronous lobe encounters, (4) magnetic field line models and field line mapping; (5) outer plasmasphere shape, configuration and dynamics; and (6) local plasma processes. This paper briefly highlights the MPA-related work in each of these areas. In addition, a list of ongoing MPA studies is provided; other collaborative uses of these data are strongly encouraged. DOE

COMPARISON OF METEOROLOGICAL DATA WITH FITTED VALUES EXTRACTED FROM PROJECTILE TRAJECTORY Final Report, Jul. 1993 - Jul. 1994
Gene R. Cooper and Kevin S. Fansler Oct. 1994 35 p
(AD-A285921; ARL-TR-603) Avail: CASI HC A03/MF A01

In this report, the atmospheric conditions are found by knowing only the projectile's flight trajectory and its flight coefficients together with the initial atmospheric conditions on the ground. The test trajectories were generated as solutions of the modified point mass (MPM) equations of motion. The correct atmospheric conditions for the generated flight trajectory are obtained from data collected during a weather balloon flight. A nonlinear least squares method was then used to fit the MPM equations to the test trajectory by varying the meteorological parameters. Density, sound speed, and wind profiles agreed well. Further tests of the method involved the flight coefficients, which we perturbed to observe the corresponding variation for the fitted values. Also, Gaussian noise was introduced onto the trajectory values to simulate the uncertainty in trajectory measurements. The results of the analysis shows that the whole trajectory should be fitted, and not small trajectory segments, to obtain accurate atmospheric parameters with the location precision provided by current radar and Global Positioning Satellite System (GPS) techniques. THE INITIATION OF LIGHTNING AND THE GROWTH OF ELECTRIC FIELDS IN THUNDERSTORMS Final Report, 1 Nov. 1991 - 31 Mar. 1994
John Latham Dec. 1993 60 p
(Contract F49620-92-J-0020)
(AD-A280033; UMIST/PHYS/2; AFOSR-94-0317TR) Avail: CASI HC A04/MF A01

Further research into the glaciation of convective clouds of-the type that produce lightning has revealed that the early stages of ice formation can be detected by measurement of the supercooled droplet radius - a result which also has climatological implications. Further laboratory experiments have shown that the most effective methods of lightning initiation are likely to involve supercooled raindrops, with threshold fields around 300kV/m. A new model of thundercloud electrification and lightning production has been developed, from which it is possible to deduce the sensitivity of lightning frequency to meteorological and cloud microphysical parameters. MONSOONS: AMIP SIMULATIONS OF THE 1987 AND 1988 DROUGHT AND FLOOD REGIMES
K. R. Sperber and T. N. Palmer (European Centre for Medium-Range Weather Forecasts, Reading, England.) Oct. 1993 6 p Presented at the 18th Climate Diagnostics Workshop, Boulder, CO, 1-5 Nov. 1994
(Contract W-7405-eng-48)
(DE94-014789; UCRL-JC-114511; CONF-941193-1) Avail: CASI HC A02/MF A01

The simulation of monsoons, in particular the Indian summer monsoon, has proven to be a critical test of a general circulation models ability to simulate tropical climate and variability (Simulation of Monsoon Variability, WCRP-68, 1992). In an effort to better understand the necessary conditions for the simulation of a phenomenologically correct Indian Monsoon, we present analyses of simulations associated with the Atmospheric Model Intercomparison Project, a coordinated effort to simulate the 1979-88 decade using standardized boundary conditions with approximately 30 atmospheric general circulation models. Diagnostics, such as those performed under the auspices of the Monsoon Numerical Experimentation Group have been evaluated to address questions regarding the predictability of monsoon extremes. Particular attention has been devoted to the 1987 and 1988 Indian monsoon drought and flood regimes associated with El Nino and La Nina conditions in the Pacific. DOE

Artificial neural networks (ANN's) have been shown capable of simulating the behavior of complex, nonlinear, systems, including structural systems. Under certain circumstances, it is desirable to simulate structures that are analyzed with the finite element method. For example, when we perform a probabilistic analysis with the Monte Carlo method, we usually perform numerous (hundreds or thousands of) repetitions of a response simulation with different input and system parameters to estimate the chance of specific response behaviors. In such applications, efficiency in computation of response is critical, and response simulation with ANN's can be valuable. However, finite element analyses of complex systems involve the use of models with tens or hundreds of thousands of degrees of freedom, and ANN's are practically limited to simulations that involve far fewer variables. This paper develops a technique for reducing the amount of information required to characterize the response of a general structure. We show how the reduced information can be used to train a recurrent ANN. Then the trained ANN can be used to simulate the reduced behavior of the

original system, and the reduction transformation can be inverted to provide a simulation of the original system. A numerical example is presented.

EFFECTS OF MICROPHYSICS AND RADIATION ON MESOSCALE PROCESSES OF A MIDLATITUDE SQUALL LINE
Hung-Neng Steve Chin Apr. 1994 6 p Presented at the 6th Conference on Mesoscale Processes, Portland, OR, 18-22 Jul. 1994
(Contract W-7405-eng-48)
(DE94-014732; UCRL-JC-115990; CONF-940769-7) Avail: CASI HC A02/MF A01

The understanding of the essential dynamics of mesoscale convective systems (MCS's) was well addressed in the literature. Effects of different physics on mesoscale processes of MCS's are, however, not well understood at some particular aspects, such as the origins of the rear inflow and the transition zone in the radar reflectivity. Attention is focused on these two aspects for a midlatitude broken-line squall system. The existence of the rear inflow in MCS's has been identified in many observational and modeling studies. Although convincing evidence has shown that physical processes internal to the mesoscale system and pressure gradient effects in the convective and trailing stratiform regions are undoubtedly important in developing the rear inflow, it remains unclear how these internal processes interact with pressure effects to trigger the rear inflow. Moreover, many modeling studies have replicated the bright melting band, but the transition zone has not been successfully simulated. With the enhanced model physics, such as radiation, in a cloud model, we can simulate these features and provide some supplemental evidences, at least in part, to explain them. The modulation of the rear inflow by microphysics, longwave (LW) and shortwave (SW) radiation, and its related cloud-radiative feedback to the modeled squall line system are also discussed. DOE

THE VERTICAL DISTRIBUTION OF HEATING IN THE TROPICAL ATMOSPHERE Annual Report, 1 Oct. 1991 - 30 Sep. 1994
William M. Frank 30 Sep. 1994 5 p
(Contract N00014-92-J-1069)
(AD-A285934) Avail: CASI HC A01/MF A01

This grant supported research is in two areas. The primary goal of the work was to plan and participate in the TOGA-COARE (Tropical Ocean-Global Atmosphere Couple Ocean-Atmosphere Experiment) program to analyze large-scale heat and moisture budgets with the data from that experiment. The second major goal was to analyze relationships between large-scale tropical circulations and tropical cyclone intensity changes in the Northwest Pacific. Research has gone very well in both areas. DTIC

MESO-SCALE COOLING EFFECTS OF HIGH ALBEDO SURFACES: ANALYSIS OF METEOROLOGICAL DATA FROM WHITE SANDS NATIONAL MONUMENT AND WHITE SANDS MISSILE RANGE
B. Fishman, H. Taha, and H. Akbari 20 May 1994 30 p
(Contract DE-AC03-76SF-00098)
(DE94-018535; LBL-35056) Avail: CASI HC A03/MF A01

Urban summer daytime temperatures often exceed those of the surrounding rural areas. Summer 'urban heat islands' are caused by dark roofs and paved surfaces as well as the lack of vegetation. Researchers at Lawrence Berkeley Laboratory are interested in studying the effects of increasing the albedo of roof tops and paved surfaces in order to reduce the impacts of summer urban heat islands. Increasing the albedo of urban surfaces may reduce this heat island effect in two ways, directly and indirectly. The direct effect involves reducing surface temperature and, therefore, heat conduction through the building envelope. This effect of surface albedo on surface temperatures is better understood and has been quantified in several studies. The indirect effect is the impact of high albedo surfaces on the near surface air temperatures. Although the indirect effect has been modeled for the Los Angeles basin by Sailor, direct field observations are required. The objective of this report is to investigate the meso-scale climate of a large high albedo area and identify the effects of albedo on the near surface air temperature. To accomplish this task, data from several surface weather stations at White Sands, New Mexico were analyzed. This report is organized into six sections in addition to this introduction. The first gives the general geological, topographic, and meteorological background of White Sands. The second is a discussion of the basic surface meteorology of the White Sands region. This section is followed by a general discussion of the instrumentation and available data. The fourth section is a description of the method used for data analysis. The fifth section which presents the results of this analysis. Finally, the last section is the summary and conclusion, where a discussion of the results is presented. DOE

A STUDY OF WESTERLY WIND BURSTS PRECEDING THE 1991-1992 EL NINO Final Report
Patricia A. Phoebus and John C. Kindle Jul. 1994 57 p
(AD-A286570; NRL/FR/7531-94-9450) Avail: CASI HC A04/MF A01

Anomalous westerly wind events in the western equatorial Pacific are of interest because of their potential to generate equatorially trapped ocean Kelvin waves that may be related to the development or enhancement of the El Nino. While a number of ideas have been proposed about the nature and origin of the equatorial westerlies, detection and description of these events is hindered by the lack of observational data in the area of interest (3 deg S-3 deg N, 130 deg E-180 deg E). Under such circumstances, the best tool for obtaining a realistic representation of the atmosphere is a four-dimensional global data assimilation system which continually updates a short-term model forecast using synoptic data to produce meteorological fields that are consistent with known dynamical and physical relationships. Using low-level wind fields from the U.S. Navy's operational global analysis/forecast system for the period October 1990-February 1992, we observed a clear association between significant westerly wind events and tropical cyclone development. In general, there is an eastward and equatorward shift in cyclone activity that is associated with the concentration of westerlies along the equator in the western and central Pacific. The strongest westerlies are associated with the development of dual-hemisphere cyclone pairs, and these events preceded the maximum warming in the eastern Pacific by a couple of months, thus supporting the hypothesis for ocean Kelvin wave contributions to the El Nino. Similar patterns in tropical cyclone activity are observed during other years marking the beginning of the El Nino. DTIC

TEST AND EVALUATION MASTER PLAN (TEMP) FOR THE WEATHER MESSAGE SWITCHING CENTER REPLACEMENT (WMSCR)
William Benner, Nannette Gordner, and David Roth Oct. 1994 46 p
(AD-A286590; DOT/FAA/CT-TN94/38) Avail: CASI HC A03/MF A01

The Weather Message Switching Center Replacement (WMSCR) Test and Evaluation Master Plan (TEMP) outlines the Test and Evaluation (T and E) process that will be used to ensure that the WMSCR meets the requirements of both the project specification and the requirements allocated from the National Airspace System (NAS) documents. It provides strategy and guidance for test requirements. The WMSCR TEMP has been prepared in accordance with FAA Order 1810.4B and FAA-STD-024a. The WMSCR TEMP follows the requirements defined in FAA-E-2764c, WMSCR Requirements Specification. This TEMP is a high-level document that related required system characteristics and critical issues to test objectives. It addresses Developmental Test and Evaluation (DT and E), Production Acceptance T and E (PAT and E), Operational T and E (OT and E) for System Shakedown (OT and E Shakedown). The TEMP also outlines procedures to be followed to ensure the successful integration of the WMSCR system into the NAS. Testing is performed to ensure integration of new subsystems will not degrade the current operations of the NAS.

BALLOON TRACKING FOR THE ASTEX/MAGE LAGRANGIAN EXPERIMENT
Steven Businger Apr. 1994 24 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-92-J-1285)
(AD-A280078) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The Lagrangian experiments in Atlantic Stratocumulus Transition Experiment/Marine Aerosol Gas Exchange (ASTEX/MAGE) were the first attempt to repeatedly sample the same remote marine air parcel over an extended period (36 to 48 hours), permitting observation of chemical changes in the sulfur budget (in particular, the formation of sulfate aerosol from biogenic DMS gas) while limiting the complication of advection through the sampling area. Our goal in supporting the Lagrangian experiments is to provide tetroon location data and analysis of relevant meteorological data to provide an unambiguous track of a chosen volume of air, estimate the entrainment through the MBL inversion, and estimate the impact of air-mass divergence. PROCEEDINGS OF THE CLOUD IMPACTS ON DOD OPERATIONS AND SYSTEMS 1993 CONFERENCE (CIDOS 1993) Interim Report
D. D. Grantham 1 Jul. 1994 510 p Conference held in Fort Belvoir, VA, 16-19 Nov. 1993
(AD-A286658; PL-TR-94-2188; ERP-1152) Avail: CASI HC A22/MF A04

The Tri-Service Cloud Modeling Program was established by OUSDR&E and is chaired by the Phillips Lab., Geophysics Directorate. As part of this program, the CIDOS conference is held at 18 month intervals. This forum was attended by over 150 researchers and DOD systems designers/users to exchange information on requirements and ongoing research for cloud effects of weapon, communication, and surveillance systems. The theme of CIDOS-93 was Clouds; The First Order Impact-For Defense and Civil Simulations. A Keynote address entitled 'Modeling and Simulation-To Fight the Future...Harness the Power of Simulation' was presented by Lt. Col. David Bartlett, Defense Modeling Simulation Office, United States Marine Corps. Three and a half days of CIDOS-93 were devoted to oral and poster presentations in six sessions: (1) Introduction and Program Reviews, (2A) Simulation Support, (2B) Analysis and Applications, (2C) Forecasting, (3) Systems and Sensors, and (4) Databases. The final session consisted of workshop meetings on two topics; Simulation Support and Cloud Microphysical Impacts Military Systems Support (e.g. Ship/Aircraft Tracks). Summaries of these are included in Part 1 of this document. DTIC

GLOBAL IONOSPHERIC WEATHER
Dwight T. Decker and Patricia H. Doherty 28 Feb. 1994 45 p
(Contract F19628-93-K-0001)
(AD-A285520; PL-TR-94-2147; SR-1) Avail: CASI HC A03/MF A01

In the last year, we have studied several issues that are critical for understanding ionospheric weather. Work on global F-region modeling has consisted of testing the Phillips Laboratory Global Theoretical Ionosphere Model. Comparisons with both data and other theoretical models have been successfully conducted and are ongoing. GPS observations, as well as data analysis, are also ongoing. Data have been collected for a study on the limitations in making absolute ionospheric measurements using GPS. Another study on ionospheric variability is the first of its kind using GPS data. The observed seasonal total electron content behavior is consistent with that determined from the Faraday rotation technique. Work on the FAA's Phase 1 Wide Area Differential GPS (WADGPS) Satellite Navigation Testbed Experiment also continues. Initial results indicate that stations using operational WADGPS should be located no greater than 430 km apart. Work comparing our electron-proton-H atom model to both observations and other models has been generally successful. We have successfully modeled the creation of high-latitude large-scale plasma structures using two separate mechanisms (time-varying global convection and meso-scale convection events). DTIC

APPLICABILITY OF THE ECMWF RAIN HEIGHT AND RAINFALL RATE DATA TO THE PREDICTION OF LOW-AVAILABILITY RAIN ATTENUATION IN EUROPE
Seppo Karhu, Sakari Uppala (Finnish Meteorological Inst., Helsinki, Finland.), and Erkki Salonen May 1994 63 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(ISSN 0355-5712)
(PB95-127684; ISBN-951-22-2143-8) Avail: Issuing Activity (National Technical Information Service (NTIS))

In this report the purpose is to evaluate the different estimates of the rain height, based on the ECMWF grid data, and to compare them with the results and the models available from the literature. The Rice-Holmberg rainfall rate model and its input parameters from the ECMWF are also assessed in many ways. The objective is to decide whether the Rice-Holmberg model is sufficiently good in the estimation of the rainfall rate statistics for low rainfall rates. Since the rain heights and the Rice-Holmberg input parameters are intended for the prediction of rain attenuation at the low-availability range of annual time percentages in Europe, the ultimate test of their applicability for this purpose is presented in the companion report, where cumulative distributions of the predicted atmospheric attenuation, including attenuation due to rain, are compared with the distributions of the measured atmospheric attenuation. AN INTEGRATED CLOUD OBSERVATION AND MODELING INVESTIGATION IN SUPPORT OF THE ARM PROGRAM
1994 9 p
(Contract DE-FG02-90ER-61071)
(DE95-002798; DOE/ER-61071/T1) Avail: CASI HC A02/MF A01

Work continued on the development of techniques for defining cloud properties from the 94 GHz cloud radar. Information, in the form of a submitted manuscript, has been developed about the use of radar to determine cloud boundary statistics and cloud structure with specific applications to marine boundary layer clouds, a mid-latitude cyclone, and cirrus. In addition a comparison of the aircraft and radar observations and a description of how data from the radar can be combined with other remote sensing systems is included. Mesoscale numerical modelling within the Penn State DOE-ARM research program has continued. In order to study the response of clouds to various forcing functions, development continues on a detailed numerical model of the microphysical processes known to operate in the atmosphere during the cloud and precipitation formation. UNIFIED VERY LOW STRATUS CLOUD/SUBCLOUD MICROPHYSICS MODEL: USER'S GUIDE Final Report
Neal H. Kilmer Jul. 1994 100 p Sponsored by Army Research Lab. Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A286454; ARL-CR-96) Avail: CASI HC A05

Use of computer program MACACASM is described. MACACASM is based on the Rachele-Kilmer microphysics model for simulating very low stratus clouds and their associated subcloud regions. This model uses the assumption that the atmosphere contains particles that grow in the presence of moisture as a function of relative humidity, temperature, and the size and chemistry of the particles. Components of this model include droplet growth and evaporation, phase change and mass balance of total water, thermodynamics, and ascent of a cluster of drops enclosed in moist air. User input includes some conventional meteorological values at a reference height near ground level and some parameter values and other specifications. Vertical profiles of drop size distributions can be simulated and used for further analysis. Examples of further use of drop size distribution profiles include simulation of profiles of extinction, backscatter, absorption, and scattering coefficients. The first part of this guide is intended for the scientist-user. The second part has been prepared for the computer programmer who may be developing other programs related to this model. DTIC

CLIMATOLOGICAL DATA FOR CLOUDS OVER THE GLOBE FROM SURFACE OBSERVATIONS, 1982-1991: THE TOTAL CLOUD EDITION

C. J. Hahn (Colorado Univ., Boulder, CO.), S. G. Warren (Washington Univ., Seattle, WA.), and J. London (Colorado Univ., Boulder, CO.) Oct. 1994 46 p

(Contract DE-AC05-84OR-21400)

(DE95-002537; ORNL/CDIAC-72; NDP-026A) Avail: CASI HC A03/MF A01

Routine, surface synoptic weather reports from ships and land stations over the entire globe, for the ten-year period December 1981 through November 1991, were processed for total cloud cover and the frequencies of occurrence of clear sky, precipitation, and sky-obscured due to fog. Archived data, consisting of various annual, seasonal and monthly averages, are provided in grid boxes that are typically 2.5 deg x 2.5 deg for land and 5 deg x 5 deg for ocean. Day and nighttime averages are also given separately for each season. Several derived quantities, such as interannual variations and annual and diurnal harmonics, are provided as well. This data set incorporates an improved representation of nighttime cloudiness by utilizing only those nighttime observations for which the illuminance due to moonlight exceeds a specified threshold. This reduction in the night-detection bias increases the computed global average total cloud cover by about 2%. The impact on computed diurnal cycles is even greater, particularly over the oceans where is found, in contrast to previous surface-based climatologies, that cloudiness is often greater at night than during the day. DOE

SAR-RELATED STRESS VARIABILITY IN THE MARINE ATMOSPHERIC BOUNDARY LAYER (MABL) Annual Report

Hampton N. Shirer and George S. Young 1994 12 p Sponsored by ONR Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(AD-A286462) Avail: CASI HC A03

By variably stressing the sea surface, secondary circulations within the marine atmospheric boundary layer (MABL) can modulate the sea surface wave field and so can produce discernible signatures on synthetic aperture radar (SAR) images of the ocean. Our most immediate goal is to determine how effective these two and three dimensional buoyantly forced MABL circulations are in producing patterns of sea-surface stress variability that can be directly linked to the quasilinear and cellular SAR signatures that were observed during the two HI-RES ARI cruises and by satellite mounted sensors. Our approach is to combine observational and modeling studies of the various secondary circulations in the MABL to determine their contributions to stress variability at the sea surface. Analysis of ship observations and model results suggest that a solenoidal circulation, dynamically akin to the classic sea-breeze circulation, causes the significant MABL wind variations observed in the vicinity of the northwest wall of the Gulf Stream. The preliminary results from the two and three dimensional models indicate that the stress variability patterns at the sea surface are reasonable. CASI

TESTS OF AN IMPROVED OCEANOGRAPHIC EXPERT SYSTEM Final Report

Matthew Lybanon 4 May 1994 10 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(AD-A280123; NRL/MR/7240-94-7517) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

For 8 years the Naval Research Laboratory's Remote Sensing Applications Branch has been developing an oceanographic expert system (OES) that models some aspects of the kinematics of the Gulf Stream and its associated eddies. The OES uses a rule base to provide ring-motion forecasts and a neural network to forecast Gulf Stream motion. Previous work showed that OES forecasts of ring motion are at least as good as those produced by other methods. Recent work led to improvements in the ring-motion geometry equations, replacement of the Gulf Stream motion logic, and the addition of a natural-language explanation facility. The first two changes required 'retuning' of the OES. The changes were designed to remove linear trends in the mean forecast position errors for noninteracting (with the Gulf Stream) rings. This report presents a comparison of the present system's performance with 'prototype' and improved parameters. For noninteracting rings, the improved system provides ring-motion forecasts that are superior to a no-motion assumption 75% or more of the time for both warm-core rings and cold-core rings, for both 7-day and 14-day forecasts. The forecast ring positions are within 20 km of the true positions. This report provides more complete information on the OES and the test results. DTIC

THE SURFACE WAVE DYNAMICS EXPERIMENT (SWADE): A RETROSPECTIVE LOOK AT THE WAVE MODELING ACTIVITIES

R. E. Jensen Sep. 1994 12 p

(AD-A285612; CERC-94-3) Avail: CASI HC A03/MF A01

Approximately four years ago a group of internationally known researchers in meteorology, air-sea interactions, and wave theory met for the last of many preliminary meetings finalizing their respective tasks for the Surface Wave Dynamics Experiment (SWADE) to commence in October 1990 off the DelMarVa peninsula. Not since the Joint North Sea Wave Project had there been a concentrated measurement program investigating the evolution of wave spectra in deep water. This experiment was timely because new and improved in situ measurement methods and advancement of remote sensing devices had come of age in the estimation of high-resolution directional spectra, providing the basis to support a new generation of spectral wave models under development. RADIANCE OF THE OCEAN HORIZON Final Report

C. R. Zeisse Apr. 1994 103 p

(AD-A285613; NRAD-TR-1660) Avail: CASI HC A06/MF A02

Cox and Munk proposed that the fluctuating surface of the open ocean could be accurately represented by many small mirror-like facets, each of which is randomly tilted with respect to the local horizon. Through aerial photographs of sun glint, they determined the statistical distribution of capillary wave slopes as a function of wind velocity. However, when their equation connecting the slope distribution with sun glint is used on the horizon, an infinite glint is predicted even though it can easily be shown that sun glint should never exceed solar radiance. The objective of this report is to remove the infinite horizon radiance from the Cox-Munk model of the ocean surface. DTIC

A MODAL ANALYSIS OF CURRENTS IN A PACIFIC ATOLL LAGOON M.S. Thesis

Burton T. Palmer Jun. 1994 178 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(AD-A283721) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The results of an initial quantitative study to define the physical oceanography of Johnston Atoll's lagoon circulation is presented. A bathymetric data base of the Island has been manually digitized from Navigational charts. A numerical model designed to predict the seiche modes of basins in two and three dimensions, in elliptic and Cartesian coordinates is developed, which seems to represent accurately the free modes of oscillation observed in current meter records. The numerical model is suitable for applications using a personal computer equipped with MATLAB (4.0) or later, and has applicability to basins of arbitrary shape in two dimensions, and rectangular, elliptical or circular symmetry in three dimensions. An analysis of currents within the lagoon at Johnston Atoll shows highly polarized tidal flow, phase locked to the diurnal tide. Spectral energy content of current meter records show six fundamental oscillatory modes and harmonics of tidal components. DTIC

OCEANOGRAPHIC ANALYSIS OF THE ACOUSTIC MID-OCEAN DYNAMICS EXPERIMENT Final Report, 1 Nov. 1992 - 30 Jun. 1994

Peter Worcester, Bruce Cornuelle, and David Chester 30 Sep. 1994 6 p
(Contract N00014-93-1-0461)
(AD-A285907) Avail: CASI HC A02/MF A01

Reciprocal acoustic transmissions made in the Northwest Atlantic have been analyzed to determine the general circulation of the region between Bermuda and Puerto Rico. Six tomographic transceivers were moored from March 1991 to March 1992 in the region centered at 25 deg N, 66 deg W during Acoustic Mid-Ocean Dynamics Experiment (AMODE). The goals of the research performed under this contract have been: (1) to study large-scale (300 to 1000 km) circulation and variability in temperature, current, and relative vorticity fields; (2) to study mesoscale eddy kinematics and dynamics; and (3) to study the value of integral constraints on eddy-resolving numerical ocean models. Large-scale range averages (over 300 to 700 km sections) of temperature and velocity and large-scale areal averages (over regions comprising 100,000 sq km of relative vorticity in the upper 3500 m of the water column have been estimated through inversion of the tomographic travel time data. ATLAS OF SSM/I SATELLITE ICE CONCENTRATION INTERPOLATED TO OPERATIONAL ICE MODEL DOMAINS OF THE ARCTIC FOR 1993 Final Report

G. N. Lundeen, R. H. Preller, P. G. Posey, and A. Cheng 5 May 1994 355 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(NR Proj. X20-08)
(AD-A280183; NRL/MR/7322-94-7524) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The Navy's Polar Ice Prediction System, which is run daily at the Fleet Numerical Meteorology and Oceanography Center (FNMOC), is initialized once each week from ice concentration data derived by the Navy/National Oceanic and Atmospheric Administration National Ice Center (formerly the Joint Ice Center). Ice concentration data, derived by applying the U.S. Navy's algorithm to the Defense Meteorological Satellite Program Special Sensor Microwave Imager (SSM/I) data, have been collected from FNMOC on a daily basis and archived at the Naval Research Laboratory. These data were then interpolated to the operational ice model grids for possible use as a real-time daily update to the operational forecast systems. Collection of data with coverage from the Pole southward to 20 deg N allows for the observation of ice concentrations for the entire Arctic region and surrounding coastal seas. SSM/I ice concentration data from 1993 are presented for each available day and on each of the operational model grids. DTIC

ANALYSIS OF LOW FREQUENCY OCEAN NOISE. 1: FROM A LONG-TERM EXPERIMENT ACROSS THE US EAST COAST. 2: FROM THE WAKE ISLAND HYDROPHONE ARRAY DURING NORTHWEST PACIFIC TYPHOONS

Charles S. McCreery, Frederick K. Duennebier, and Daniel A. Walker 22 Jul. 1994 149 p
(Contract N00014-90-J-1683)
(AD-A284975) Avail: CASI HC A07/MF A02

The East Coast experiment, called the Environmentally Controlled Ocean floor NOise Monitoring Experiment (ECONOMEX), was designed to sample ambient noise in the water column and on the ocean floor across the continental shelf and slope east of Chesapeake Bar. A vertical array of hydrophones in the water column, a horizontal array of hydrophones, and three-component seismometers were deployed for several months in the spring of 1991. The experiment was designed to coincide with the Surface WAve Dynamics Experiment (SWADE) in order to take advantage of their extensive measurements of surface winds and directional ocean wave spectra in the same region. This comprehensive and long-term data set permits the identification of specific noise generation and propagation mechanisms for the continental shelf and slope, and evaluation of their contribution to the noise field under a wide variety of ocean surface conditions. The primary goal of studying data from the Wake Island Hydrophone Array is to quantify changes in the noise field due to the extreme ocean surface conditions produced by typhoons, and to identify mechanisms by which these storms produce noise. MISSISSIPPI STATE UNIVERSITY CENTER FOR AIR SEA TECHNOLOGY FY 1993 AND FY 1994 RESEARCH PROGRAM IN NAVY OCEAN MODELING AND PREDICTION Final Technical Report

Lanny A. Yeske and James H. Corbin 30 Sep. 1994 73 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-92-J-4109)
(AD-A286322; CAST-TR-94-3) Avail: CASI HC A04

The Mississippi State University Center for Air Sea Technology (CAST) began operation on 1 Oct. 1992 under a two-year research grant (N00014-92-J-4109) issued by the Office of Navy Research. This final technical report is submitted in accordance with requirements contained in the grant. Included is a discussion of the FY93 (1 Oct. 1992 - 30 Sep. 1993) research program under the Experimental Center for Mesoscale Ocean Prediction Project with its tasks of ocean model initialization and evaluation data; ocean model verification, evaluation, and transition; and scientific visualization for model evaluation. This is followed by the FY94 (1 Oct. 1993 - 30 Sept. 1994) program which was reorganized into the Coastal and Semi-Enclosed Seas Relocatable Models Project (6.1), the Ocean Model Technology Project (6.2), and the Advanced Development and Transitions Project (6.3). Also included is a discussion of the planned research for FY95 and FY96. This is followed by Appendix 1 which summarizes eight other contracts obtained by CAST with the Naval Research Laboratory, Naval Oceanographic Office, Army Corps of Engineers Coastal Engineering Research Center, Gulf Weather Corporation, Department of Defense, and Office of Naval Research. Finally, Appendix 2 summarizes CAST publications completed during this two year period as well as other CAST accomplishments. DTIC

AMBIENT NOISE AND SURFACE WAVE DISSIPATION IN THE OCEAN Ph.D. Thesis

Francis C. Felizardo Jun. 1993 221 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A279650) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

There is a growing consensus that the sound generated by breaking waves is responsible for much of the ambient noise level in the ocean. While numerous field measurements have shown a strong correlation between the ambient noise spectrum level (N) in the range 100 Hz to 25 kHz and wind speed in the ocean, very little has been done to establish a comparable correlation between the ambient noise spectrum level and surface wave field parameters. The difficulty in establishing this relationship is remarkable given that the frequency and intensity of wave breaking are dependent on the characteristics of the wave field. In Fall 1991, an experiment was conducted from the research platform Flip 130 kilometers off the coast of Oregon, where the ambient noise between 2.5 and 25 kHz, the wind speed, and the sea surface elevation using wire wave gauges were measured. The correlation between N and the root mean square wave amplitude (a) was found to be poor but could be improved if the swell was filtered out from the wave elevation time series. The influence of swell on the value of a was disproportionate to the level of ambient noise since its characteristics were not directly due to the local wind-wave conditions. Observations of the dependence of the high frequency wind waves and the directional wave spectrum under turning winds suggested that the high frequency wave components responded more quickly to changes in the wind speed and direction than the energy-containing frequencies. DTIC

MODEL-BASED INVERSION FOR A SHALLOW OCEAN APPLICATION
J. V. Candy and E. J. Sullivan (Naval Undersea Warfare Center, Newport, RI.) Mar. 1994 11 p Presented at the Inversion Methods in Ocean and Seismic Acoustics Conference, La Spezia, Italy, 27 Jun. 1994
(Contract W-7405-eng-48)
(DE94-016968; UCRL-JC-115131; CONF-9406241-1) Avail: CASI HC A03/MF A01

A model-based approach to invert or estimate the sound speed profile (SSP) from noisy pressure-field measurements is discussed. The resulting model-based processor (MBP) is based on the state space representation of the normal mode propagation model. Using data obtained from the well known Hudson Canyon experiment, a noisy shallow water ocean environment, the processor is designed and the results compared to those predicted using various propagation models and data. It is shown that the MBP not only predicts the sound speed quite well, but also is able to simultaneously provide enhanced estimates of both modal and pressure-field measurements which are useful for localization and rapid ocean environmental characterization. DATA REPORT: STRESS MEASUREMENTS IN THE BOTTOM BOUNDARY LAYER WITH BASS TRIPODS STRESS 2 1990-1991
Thomas F. Gross, Julie Amft, and Albert J. Williams, III Nov. 1993 44 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contracts N00014-89-J-1058; N00014-90-J-1046)
(AD-A279875; WHOI-93-48) Avail: CASI HC A03

Two Benthic Acoustic Stress Sensor (BASS) equipped tripods were deployed in the Sediment TRansport Events on Shelves and Slopes (STRESS) experiment on the California Shelf acquiring data from January to March 1991. They measured velocity profiles in the bottom boundary layer over the lowest 5 meters. Transmissometers, thermistors, and a pressure sensor on each tripod provided suspended sediment concentration, stratification, and wave spectral information, as well. DTIC

SYNTHESIZING THE GULF STREAM THERMAL STRUCTURE FROM XBT DATA
Melinda M. Hall 14 Feb. 1994 32 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contracts N00014-87-K-0001; N00014-88-K-0612; N00014-89-J-1056; NR Proj. 083-004)
(AD-A279665; WHOI-Contrib-8394) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Thirty-six XBT temperature profiles have been used in a parametric model introduced by Hendry to model the Gulf Stream's thermal structure at 65 deg W between 200 and 1200 dbar, with an rms residual error of 0.56 C. Velocity has been computed geostrophically relative to 1200 dbar, and has been included in calculating potential vorticity analytically from the model. The resulting potential vorticity section for 65 deg W has been compared with the analogous result from Hendry's parametric model at 59 deg W, as well as observed potential vorticity sections from 68 deg to 55 deg W. There is a significant feature in the potential vorticity structure at 65 deg W not found at 59 deg W, namely a relative minimum in potential vorticity along isopycnals, centered at the Gulf Stream's axis and 350 dbar. The modelled potential vorticity sections are consistent with the observations, including the downstream disappearance of this feature. The dynamical implications of these results are briefly discussed. DTIC

MULTIPLE SCATTER THEORY OF OCEAN SEDIMENTS Technical Letter, 1 Feb. - 31 Jul. 1994
Nicholas P. Chotiros 25 Apr. 1994 7 p
(Contract N00014-94-1-0438)
(AD-A286033; TL-AS-94-07) Avail: CASI HC A02/MF A01

The long term goal was to develop a new model of acoustic bottom backscatter from sandy sediments, based on a multiple scattering theory approach, and, hence, properly explain observed phenomena, including Lambert's rule and frequency dependence of backscattering strength, particularly at shallow grazing angles, for which current theories are at a loss. MONTHLY MEAN SEA ICE DATA FROM THE POLAR ICE PREDICTION SYSTEM, THE REGIONAL POLAR ICE PREDICTION SYSTEM-BARENTS SEA AND THE REGIONAL POLAR ICE PREDICTION SYSTEM-GREENLAND SEA Final Report
P. G. Posey and R. H. Preller 6 May 1994 83 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(NR Proj. X05-13)
(AD-A280095; NRL/MR/7322-94-7525) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The Polar Ice Prediction System (PIPS), the Regional Polar Ice Prediction System - Barents (RPIPS-B) and the Regional Polar Ice Prediction System - Greenland Sea (RPIPS-G) are all operational sea ice forecasting systems that have been run daily at the Fleet Numerical Meteorology and Oceanography Center (FNMOC) since September 1987, June 1989, and October 1991, respectively. The basis for all three models is the Hibler ice model. A Dynamic Thermodynamic Sea Ice Model. Journal of Physical Oceanography 9. Modeling a Variable Thickness Sea Ice Cover. Monthly Weather Review 108. The ice models are driven by monthly mean ocean currents and deep ocean heat fluxes derived from the Hibler and Bryan A Diagnostic Ice-Ocean Model. Journal Physical Oceanography 17 coupled ice-ocean model. They are also driven by atmospheric forcing from the Navy Operational Global Atmospheric Prediction System (NOGAPS). In Fifth Conference on Numerical Weather Prediction, American Meteorological Society, Boston, Massachusetts, preprint volume, 74-79. The Description of the Navy Operational Global Atmospheric Prediction System's Forecast Model. Naval Research Laboratory, Monterey, California, NOARL Report 13. Each day a 24-h forecast of PIPS, RPIPS-B, and RPIPS-G is submitted and archived by the Naval Research Laboratory. DTIC

MODELING OPEN BOUNDARY CONDITIONS BY USING THE OPTIMIZATION APPROACH
James K. Lewis and Igor Shulman Oct. 1994 19 p
(Contract N00014-92-J-4112)
(AD-A285548; COAM-TR-1/95) Avail: CASI HC A03/MF A01

An optimization approach to prescribe open boundary conditions (OBC's) is proposed. Open boundary conditions are chosen by providing the best fit to available observations on the open boundary and to the energy flux through the open boundary. It is shown that many local open boundary conditions widely used in the oceanographic community are special cases of the derived optimized OBC's. Numerically, the proposed methods consist of the integration of the governing equations and solving the optimization problem only on the open boundary for each time step. Results of tidal simulations for a channel and the Louisiana-Texas shelf are presented and discussed. Schemes for coupling limited area coastal models with basin scale coarse models by using optimized OBC's are proposed. Preliminary simulations of coupling a fine resolution model of the Mediterranean Sea are presented and discussed. The use of optimized OBC's is shown to be better in predicting tidal amplitudes and phases compared to the use of local OBC's. DTIC

DEVELOPMENT OF A PORTABLE ICE-THICKNESS MEASURING INSTRUMENT Final Report, 7 Aug. 1992 - 15 Feb. 1994
John C. Joseph, Dennis P. Glenn, and Philip J. Joseph 14 Mar. 1994 19 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract DACA33-91-C-0030)
(AD-A279472) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

A portable instrument that can be manually placed in contact with the surface of an ice-covered body of water to non-obtrusively measure the ice thickness was developed. The instrument design is based on determining ice thickness from microwave frequency signals which are transmitted through the ice and reflect from the ice/water interface. Prior methods include drilling through the ice to manually measure its thickness and using radar equipment which is costly, time consuming, and which produces data often difficult to interpret. The ice measuring instrument produced under this contract meets its goals for performance and physical characteristics. Measurement range exceeds the required 2 to 24 inches with 1/2 inch accuracy. Ice measurements take 12 seconds on average, thickness processing takes 10 seconds, and calibration is performed in under 30 seconds. The instrument is fully portable; it is powered by an internal, rechargeable battery. The instrument is built into a transit case, which also houses accessories. DTIC

THE STRUCTURE OF TURBULENCE AND OTHER MOTIONS BENEATH AN AIR-WATER INTERFACE Final Technical Report, 1 Nov. 1990 - 31 Jan. 1994
Robert L. Street and Stephen G. Monismith 1 Feb. 1994 13 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-91-J-1200)
(AD-A279838; SU-EFML-94-1) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This is the final technical report for Grant N00014-91-J-1200, entitled 'The Structure of Turbulence and Other Motions Beneath an Air-Water-Interface.' The grant period was from 1 November 1990 through 31 January 1994. This research couples definitive physical experiments and numerical simulation experiments to study three-dimensional, unsteady, real-fluid flows beneath the air-water interface. The overall goals for the long term are to develop a complete understanding of the flow physics and a numerical simulation tool that allows accurate prediction of the motion from a specified set of initial and boundary conditions. This report covers the early period of the long term project. The numerical tool developed is for the simulation of free-surface flows through the solution of the time-dependent, incompressible, Navier-Stokes equations with non-linear dynamic and kinematic boundary conditions. It is being developed in three dimensions; the two-dimensional version is operational. The physical experiments have focused on developing-accurate maps of the flow fields under the waves with and without a surface piercing body. DTIC

MIXING AND DYNAMICS OF THE MEDITERRANEAN OUTFLOW Ph.D. Thesis
Molly O. Baringer Feb. 1994 244 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-90-J-1474)
(AD-A279803; WHOI-93-52) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Hydrographic and expendable current profiler (XCP) data taken during the Gulf of Cadiz Expedition in September 1988 are analyzed here to understand the mixing and dynamics of the Mediterranean outflow from the Strait of Gibraltar. Rapid entrainment of fresh North Atlantic water prevents the flow from reaching abyssal depths in the North Atlantic despite its large initial density anomaly. Dynamical ideas about mixing and stress are tested by examining the evolution of momentum and density as the flow adjusts. The flow is found to be unstable to Kelvin-Helmholtz instability in regions where intense mixing occurs. Evaluation of the cross-stream momentum balance shows the importance of advection as the flow makes a 90 degree inertial turn after exiting the Strait. The downstream momentum residuals indicate that large stresses disrupt this rapidly achieved geostrophic balance and enable the flow to cross isobaths. The intense mixing observed suggests rates of entrainment three orders of magnitude larger than typical rates of Ekman pumping in the open North Atlantic. A simple numerical model is used to test these dynamical concepts. The model predicts the evolution of the bulk properties of the Mediterranean outflow using a Froude number dependent entrainment. RESOLVING VELOCITY PROFILES WITH THE MULTI-SCALE PROFILER
D. P. Winkel, M. C. Gregg, B. M. Bell, and T. B. Sanford Oct. 1994 82 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contracts N00014-90-J-1188; N00014-90-J-1108; N00014-94-I-0079; N00014-86-K-0690)
(AD-A286446; APL-UW-TR-9414) Avail: CASI HC A05

The multiscale profiler (MSP), a freely falling dropsonde, has been used over the last 12 years to resolve oceanic shear variance at vertical scales from a few hundred meters down to nearly a centimeter. Because MSP yielded the first complete oceanic shear spectra, it is important to document the methods by which they were produced. Large scales are measured by an electromagnetic current meter (ECM), microscales by airfoil probes, and intermediate scales by an acoustic current meter (ACM). The ACM detects velocity relative to the instrument, so the platform motion must be known to determine the water velocity. Primarily, the ACM measurements are affected by tilt oscillations and by the gross (point-mass) motion of the vehicle; the former is inferred from accelerometer data, and the latter is constructed from a model of the vehicle's response to oceanic shear. Horizontal forcing on the array of drag brushes and turning blades at the tail complicates the response by causing MSP to react strongly to fluctuations with scales near the instrument's length of 4.3 m. We examine the effects of this response on spectra of the ACM measurements, noting particularly a deep notch near 0.2 cpm (cycles per meter). To account for such spectral features, the model of Hayes et al. for the TOPS dropsonde was modified so that it correctly parameterized our large tail force. We discuss the dynamics, data processing, and model formulation relevant to production of oceanic velocity profiles from the ACM data, and present analytic transfer functions, derived from Fourier transforms of the model equations, which guide selection of optimal values for the model parameters. UNDERWATER ACOUSTIC GENERATOR PHASE 2: SEA TRIAL, MARCH 1992
R. Alksne Aug. 1993 29 p
(MRL-TN-640; AR-008-268) Copyright Avail: Issuing Activity (DSTO Materials Research Lab., PO Box 50, Ascot Vale, Victoria 3032, Australia)

In support of a joint ALO-SA, DSTO, and industry program to develop a discrete low frequency towed underwater acoustic generator (UAG), a series of sea trials were conducted. These trials were conducted in the Gulf of St. Vincent and the sea west of Kangaroo Island to check the environmental and acoustic performance of a concept UAG. This report describes the UAG Phase 2 evaluation trial held in March 1992. Details and results of the trial are provided along with an assessment of the UAG performance and conclusions and recommendations for further development and tests. Author

A SIMPLE OCEAN BOTTOM HYDROPHONE WITH 200 MEGABYTE DATA CAPACITY
K. R. Peal, G. M. Purdy, D. E. Koelsch, and F. B. Wooding Jun. 1993 43 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Grants NSF OCE-89-17628; NSF OCE-90-19918)
(AD-A279478; WHOI-93-31) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The Woods Hole Ocean Bottom Hydrophone instrument records the digitized output of a single hydrophone sensor at rates between 250 and 1200 samples per second with a dynamic range of 98 dB and can be deployed at depths to 6000 meters. The unit's 200 megabyte disk recorder allows operation for periods up to 5 days. Designed for typical marine seismic refraction operational the unit is reliable and simple to deploy and recover. A detailed description is provided of the instrument design and application including transfer function, clock accuracy, data format, sample data and power requirements. DTIC

CTD CALIBRATION AND PROCESSING METHODS USED AT WOODS HOLE OCEANOGRAPHIC INSTITUTION
Robert C. Millard and Keqi Yang Oct. 1993 87 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Grant NSF OCE-91-14465)
(AD-A279507; WHOI-93-44) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Processing methods, programs, and procedures currently used to create CTD data sets at Woods Hole Oceanographic Institution (WHOI) are described. The post-acquisition data processing steps include instrument calibrations in the laboratory and data calibration at sea, CTD data transformation from a time series to a pressure series, and the water sample data processing using the World Ocean Circulation Experiment (WOCE) format guidelines. Processing software has been developed for both the MicroVAX and IBM compatible personal computers. The description of the data processing procedures is restricted to the PC system. The programs are written primarily in FORTRAN with some format-related changes required between computer systems. DTIC
